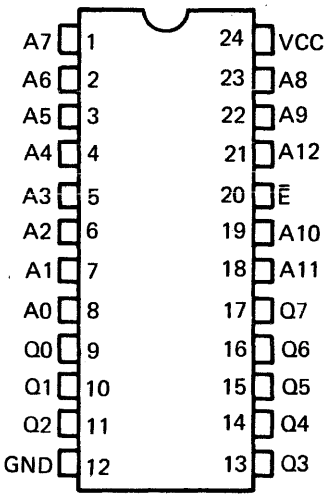
HM-6388

8192 x 8 CMOS ROM

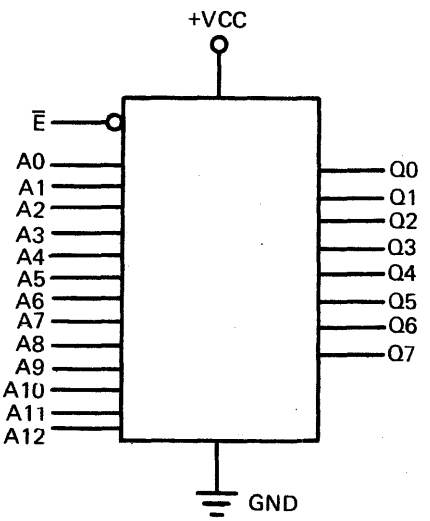
Features

- 8K WORD BY 8 BIT MEMORY
- MASK PROGRAMMED, NON-VOLATILE
- QUICK ACCESS OVER MIL TEMP. . . . . 550nsec MAX
- LOW STANDBY CURRENT OVER MIL TEMP. . . . . 100μA MAX
- SINGLE 5V POWER SUPPLY
- ON CHIP ADDRESS REGISTERS
- COMPACT 24 PIN PACKAGE
- PINOUT LIKE HM-6389 FOR EASY UPGRADE
- TTL COMPATIBLE INPUT/OUTPUT
- MILITARY, INDUSTRIAL AND COMMERCIAL TEMPERATURE RANGES



Description

The HM-6388 is a mask programmed Read Only Memory featuring quick access and extremely low power consumption. The 6388 contains internal address registers to allow simple implementation in common bus systems. Because of the similarity of pinouts a system utilizing this device can be easily modified to use the HM-6389 for added control flexibility.



Because of the large memory matrix, 65,536 bits, this device can be used for non-volatile storage of operating systems, control stores, assemblers, compilers, loaders, editors, high accuracy look up tables, and a vast number of other unique and otherwise unsatisfied applications.

Description

The HM-6389 is a mask programmed Read Only Memory featuring quick access and extremely low power consumption. The HM-6389 contains internal address registers for ease of use in common bus systems. In addition to the 65,536 bit (6K) user defined memory matrix, there are a variety of user defined control options.

These options include a Programmable Logic Array (PLA) for RAM field select allowing internal address decoding for RAM over ROM overlay memory array applications. The polarity of the RAM Field Select output is also an user option. The chip select inputs are individually definable to be active high or low, and to be latched by chip enable or nonlatched. This feature can be used to eleminate address decoding for arrays as large as 64K words. Another user defined option determines whether the data outputs will be latched by the chip enable ($\overline{E}$), or is nonlatched mode is chosen, the chip enable signal is used to disable the three state output drivers.

Because of the large data storage matrix and the versatility of the control options, this device can be used for non-volitile storage of operating systems, assemblers, compilers, loaders, editors, high accuracy look up tables, and a wide variety of otherwise unsatisfied applications.

HM-6503

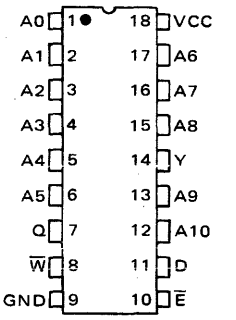
2048 x 1 CMOS RAM

Features

- LOW POWER STANDBY . . . . . ≪1mW MAX.
- LOW POWER OPERATION. . . . . 35mW/MHz MAX.
- EXTREMELY LOW SPEED POWER PRODUCT
- DATA RETENTION . . . . . @ 2.0V MIN.
- TTL COMPATIBILITY INPUT/OUTPUT
- THREE STATE OUTPUT
- FAST ACCESS TIME . . . . . 300nsec MAX.
- INDUSTRIAL OR COMMERCIAL TEMPERATURE RANGE
- 18 PIN PACKAGE FOR HIGH DENSITY
- ON CHIP ADDRESS REGISTER
- PINOUT ALLOWS UPGRADE TO 6504

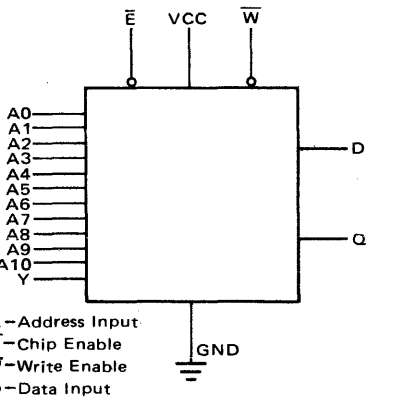
Description

The HM-6503 is a 2048 x 1 static CMOS RAM fabricated using self aligned silicon gate technology. The device utilizes synchronous circuitry to achieve high performance and low power operation.



On chip latches are provided for addresses, data input and data output allowing efficient interfacing with microprocessor systems. The data output can be forced to a high impedance for use in expanded memory arrays.

The HM-6503 is a truly static RAM and may be maintained in any state for an indefinite period of time. Data retention supply voltage and supply current are guaranteed over temperature.



The HM-6503 is supplied in two versions, the HM-6503H and the HM-6503L. The H or L is used to designate the logic level to be connected to the Y input. If a HM-6503H is procured the user must connect the Y input to VCC in the system. If a HM-6503L is used the Y input must be connected to system ground.

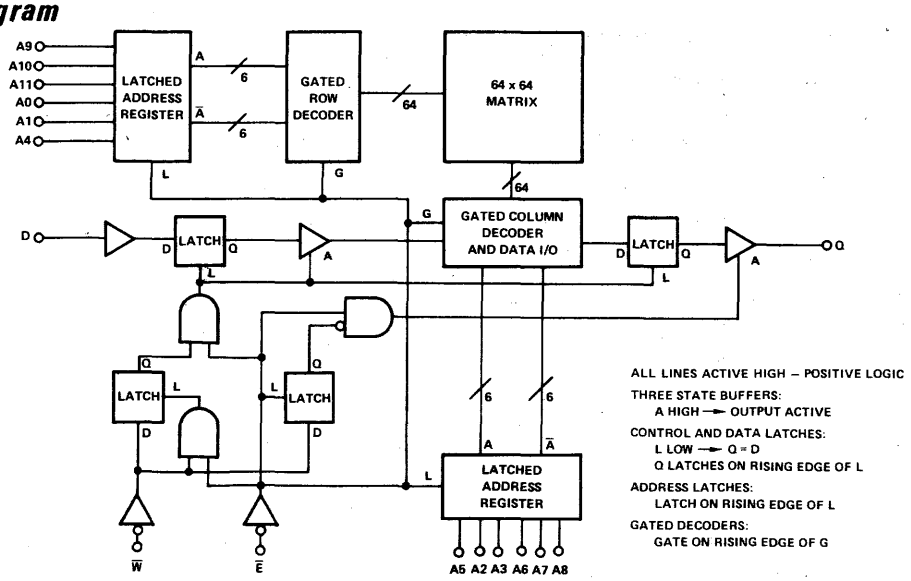
Description



The HM-6504 is a 4096 x 1 static CMOS RAM fabricated using self aligned silicon gate technology. The device utilizes synchronous circuitry to achieve high performance and low power operation.

On chip latches are provided for addresses, data input and data output allowing efficient interfacing with microprocessor systems. The data output can be forced to a high impedance for use in expanded memory arrays.

The HM-6504 is a truly static RAM and may be maintained in any state for an indefinite period of time.

Data retention supply voltage and supply current are guaranteed over temperature.

NOTES:
1. All devices tested at worst case limits. Room temp., 5 volt data provided for information — not guaranteed.
2. Operating Supply Current (ICCOP) is proportional to Operating Frequency. Example: Typical ICCOP = 1.5mA/MHz.
3. Capacitance sampled and guaranteed — not 100% tested.
4. AC Test Conditions: Inputs — TRISE = TFALL = 20nsec; Outputs — 1 TTL load and 50pF. All timing measurements at 1/2 VCC.

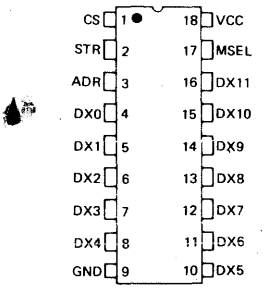
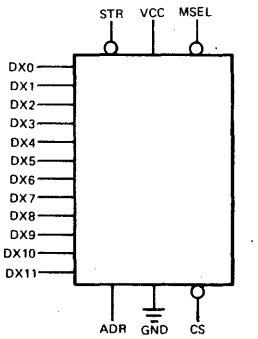
HM-6512

64 x 12 CMOS RAM



Preliminary

Features



- LOW POWER STANDBY . . . . . 1mW MAX.
- LOW POWER OPERATION. . . . . .22mW/MHz MAX.
- DATA RETENTION . . . . . @ 2.0V MIN.
- TTL COMPATIBLE INPUT/OUTPUT
- TWO HM-6512's CAN BE USED WITH HM-6100 AND HM-6312 WITHOUT ADDITIONAL COMPONENTS
- THREE STATE OUTPUTS
- FAST ACCESS TIME . . . . . .250nsec MAX.
- MILITARY AND INDUSTRIAL TEMPERATURE RANGE
- 18 PIN PACKAGE FOR HIGH DENSITY
- ON CHIP ADDRESS REGISTER

Pinout

CS — Chip Select
STR — Chip Enable
MSEL — Enable and R/W Decode
ADR — Address Decode
DX — Address Input and Data I/O

Description

The HM-6512 is a high speed, low power, silicon gate CMOS 768 bit static RAM organized 64 words by 12 bits. In all static states these units exhibit the microwatt power requirements typical of CMOS. Inputs and three state outputs are TTL compatible. The basic part operates at 4-7 volts with a typical 5 volt, 25°C access time of 150ns.

Signal polarities and functions are specified for direct interfacing with the HM-6100 microprocessor. The device is ideally suited for minimum system all CMOS applications where low power, minimum cost, or non-volatility is required.

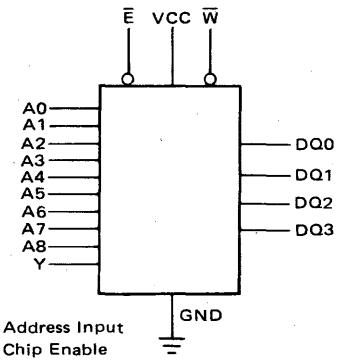
TOP VIEW

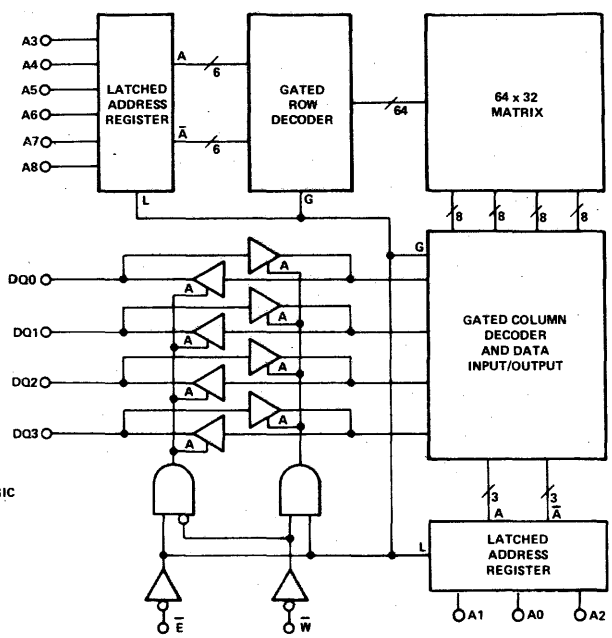
Description



The HM-6513 is a 512 x 4 static CMOS RAM fabricated using self aligned silicon gate technology. The device utilizes synchronous circuitry to achieve high performance and low power operation.

On chip latches are provided for the addresses allowing efficient interfacing with microprocessor systems. The data output can be forced to a high impedance state for use in expanded memory systems.

The HM-6513 is a fully static RAM and may be maintained in any state for an indefinite period of time. Data retention supply voltage and supply current are guaranteed over temperature.



The HM-6513 is supplied in two versions, the HM-6513H and the HM-6513L. The H or L is used to designate the logic level to be connected to the Y input. If a HM-6513H is procured the user must connect the input to VCC in the system. If a HM-6513L is used the Y input must be connected to system ground.

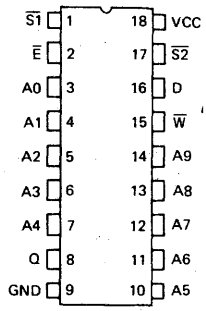
HM-6518

1024 x 1 CMOS RAM

Features

- LOW STANDBY POWER . . . . . 55μW MAX
- LOW OPERATING POWER . . . . . 22mW/MHz MAX
- FAST ACCESS TIME . . . . . 180nsec MAX
- DATA RETENTION VOLTAGE . . . . . 2.0 VOLTS MIN
- TTL COMPATIBLE IN/OUT
- HIGH OUTPUT DRIVE - 2 TTL LOADS
- HIGH NOISE IMMUNITY
- ON CHIP ADDRESS REGISTER
- TWO CHIP SELECTS FOR EASY ARRAY EXPANSION
- THREE STATE OUTPUTS
- MILITARY TEMPERATURE RANGE
- INDUSTRIAL TEMPERATURE RANGE

Description



The HM-6518 is a 1024 by 1 static CMOS RAM fabricated using self-aligned silicon gate technology. Synchronous circuit design techniques are employed to achieve high performance and low power operation.

On chip latches are provided for address and data outputs allowing efficient interfacing with microprocessor systems. The data output buffers can be forced to a high impedance state for use in expanded memory arrays.

The HM-6518 is a fully static RAM and may be maintained in any state for an indefinite period of time. Data retention supply voltage and supply current are guaranteed over temperature.

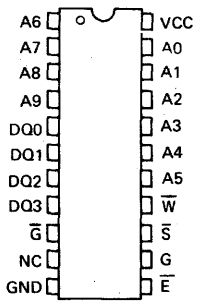
HM-6533



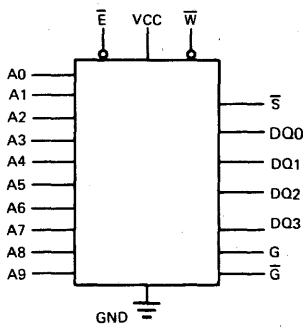
1024 x 4 CMOS RAM

Features

- LOW POWER STANDBY 1mW
- LOW POWER OPERATION. . . . . 35mW/MHz MAX
- DATA RETENTION @ 2.0 VOLTS.
- TTL COMPATIBLE INPUT/OUTPUT.
- "THREE STATE" OUTPUT.
- SEPARATE CHIP SELECT FOR EASE OF MEMORY EXPANSION.
- FULL MILITARY AND INDUSTRIAL TEMPERATURE RANGES.
- ON CHIP ADDRESS REGISTER.
- AVAILABLE IN 22 PIN DIP AND IN CHIP FORM FOR HYBRID FABRICATION.

Pinout

TOP VIEW



Description

The HM-6533 is a 1024 x 4 clocked static CMOS RAM designed specifically to interface with the HM-6100 Microprocessor. The device is manufactured utilizing self-aligned silicon gate technology. Extremely low power drain makes the HM-6533 an ideal candidate for battery powered systems.

On chip latching address registers and "Three State" I/O buffers enable the HM-6533 to operate in a multiplexed bus system with a minimum of support circuitry. Separate chip select and output disable pins allow for easy expansion. The output buffers can be disabled by the G, $\overline{G}$, or S pins (see Truth Table).

Wide supply voltage range and high noise immunity offer the system designer a large degree of flexability. Data retention is guaranteed down to 2.0V VCC making non-volitile memory systems simple to implement.

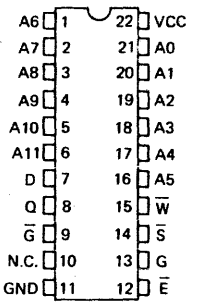
HM-6543



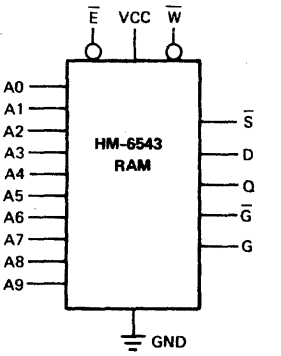
4096 x 1 CMOS RAM

Features

- LOW POWER STANDBY . . . . . 1mW MAX
- LOW POWER OPERATION . . . . . 35mW/MHz MAX
- DATA RETENTION . . . . . @ 2.0 VOLTS
- TTL COMPATIBLE INPUT/OUTPUT
- THREE STATE OUTPUT
- SEPARATE CHIP SELECT FOR EASE OF MEMORY EXPANSION
- FULL MILITARY AND INDUSTRIAL TEMPERATURE RANGE
- ON CHIP ADDRESS REGISTER
- AVAILABLE IN 22 PIN DIP AND IN CHIP FORM FOR HYBRID FABRICATION

Pinout

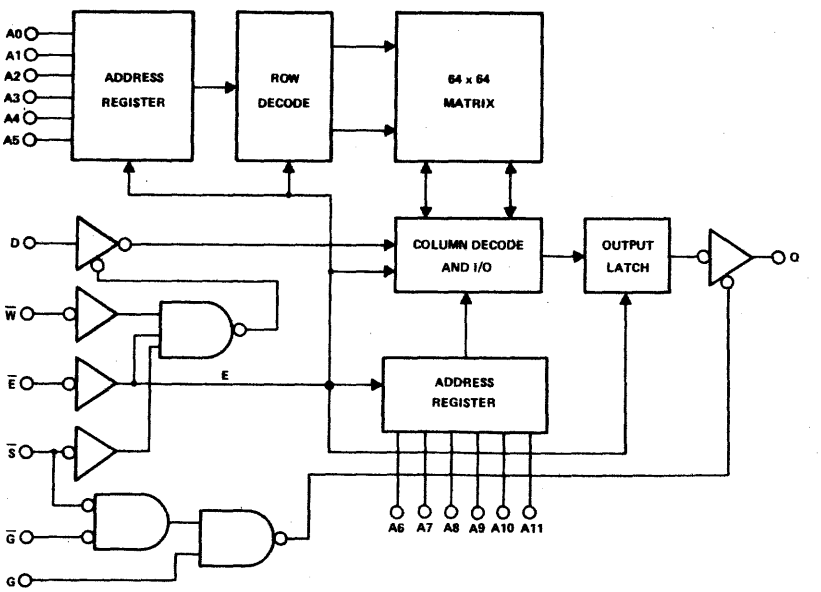
TOP VIEW



Description

The HM-6543 is a 4096 x 1 static CMOS RAM fabricated with self-aligned silicon gate technology. The device is designed to interface directly with the HM-6100, 12 bit Microprocessor.

On chip latches are provided for addresses and output data. The chip provides a three state output buffer for ease of use on a common bus.



The HM-6543 is a fully static RAM and may be maintained in any state for an indefinite period of time. Data retention, supply voltage and supply current are guaranteed over temperature.

Logic Symbol

A – Address Input

Description

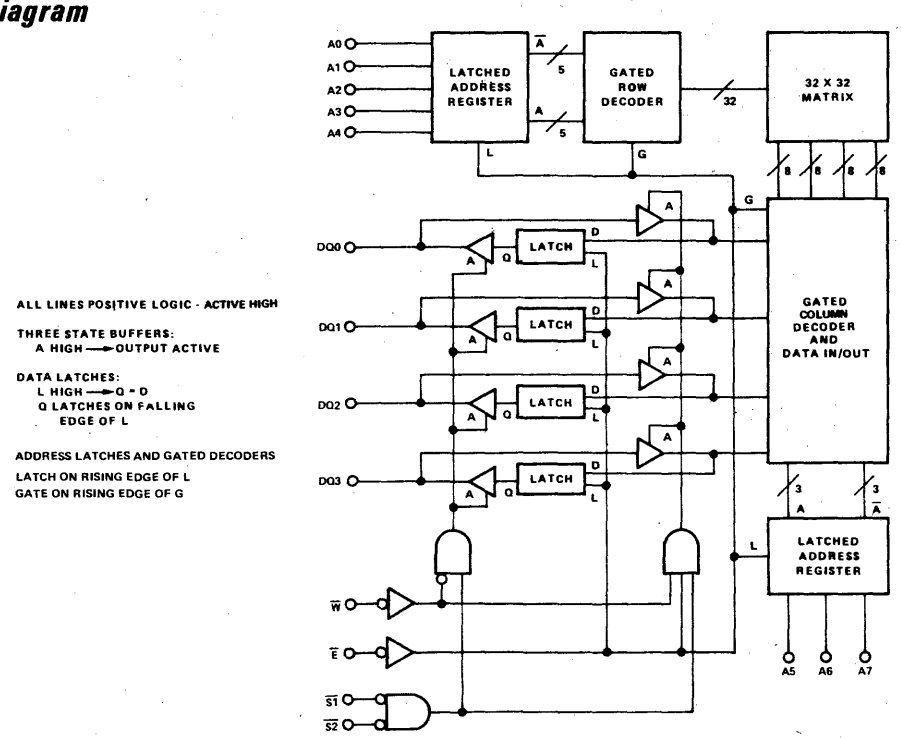
The HM-6561 is a 256 by 4 static CMOS RAM fabricated using self-aligned silicon gate technology. Synchronous circuit design techniques are employed to achieve high performance and low power operation.

On chip latches are provided for address and data outputs allowing efficient interfacing with microprocessor systems. The data output buffers can be forced to a high impedance state for use in expanded memory arrays. The data inputs and outputs are multiplexed internally for common I/O bus compatibility.



The HM-6561 is a fully static RAM and may be maintained in any state for an indefinite period of time. Data retention supply voltage and supply current are guaranteed over temperature.

The HM-6561 is pin for pin replaceable with the HM-6661, a 256 x 4 CMOS PROM. This allows a single memory board design with any organization of RAM and PROMs.

NOTES:
1. All devices tested at worst case limits. Room temp., 5 volt data provided for information — not guaranteed.
2. Operating Supply Current (ICCOP) is proportional to Operating Frequency. Example: Typical ICCOP = 1.5mA/MHz.
3. Capacitance sampled and guaranteed — not 100% tested.
4. AC Test Conditions: Inputs — TRISE = TFALL = 20nsec; Outputs — 1 TTL load and 50pF. All timing measurements at 1/2 VCC.

HM-6562

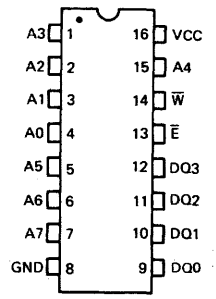
256 x 4 CMOS RAM

Features

- LOW POWER STANDBY . . . . . 55μW MAX
- LOW POWER OPERATION. . . . . 22mW/MHz MAX
- FAST ACCESS TIME . . . . . 220nsec MAX
- DATA RETENTION VOLTAGE . . . . . 2.0 VOLTS MIN
- TTL COMPATIBLE IN/OUT
- HIGH OUTPUT DRIVE – 2 TTL LOADS
- HIGH NOISE IMMUNITY
- ON CHIP ADDRESS REGISTER
- 16 PIN PACKAGE FOR HIGH DENSITY
- THREE-STATE OUTPUTS
- MILITARY TEMPERATURE RANGE
- INDUSTRIAL TEMPERATURE RANGE

Description

The HM-6562 is a 256 by 4 static CMOS RAM fabricated using self-aligned silicon gate technology. Synchronous circuit design techniques are employed to achieve high performance and low power operation.



On chip latches are provided for address allowing for efficient interfacing with microprocessor systems. The data output buffers can be forced to a high impedance state for use in expanded memory arrays. The data inputs and outputs are multiplexed internally for common I/O bus compatibility.

The HM-6562 is a fully static RAM and may be maintained in any state for an indefinite period of time. Data retention supply voltage and supply current are guaranteed over temperature.

The HM-6611, 256 x 4 CMOS PROM, is pin for pin replaceable with the HM-6562. This allows a single memory board design with any organization of RAM and PROMs.

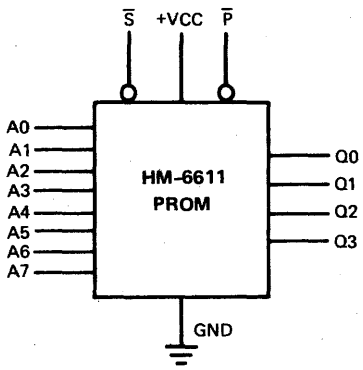
HM-6611
1024-BIT FIELD-PROGRAMMABLE CMOS PROM

Features



- FUSED LINK PROM
- FIELD-PROGRAMMABLE
- ORGANIZED 256 x 4
- LOW POWER STANDBY 0.1mW
- LOW POWER ENABLED 10mW
- CMOS RAM PINOUT EXCEPT FOR $\overline{P}$
- TTL COMPATIBLE IN/OUT
- THREE STATE OUTPUTS
- FULLY STATIC OPERATION
- FAST ACCESS TIME . . . . . 450nsec MAX
- HIGH NOISE IMMUNITY
- HIGH RELIABILITY
- MILITARY TEMPERATURE RANGE
- INDUSTRIAL TEMPERATURE RANGE
- 10 VOLT VERSION AVAILABLE

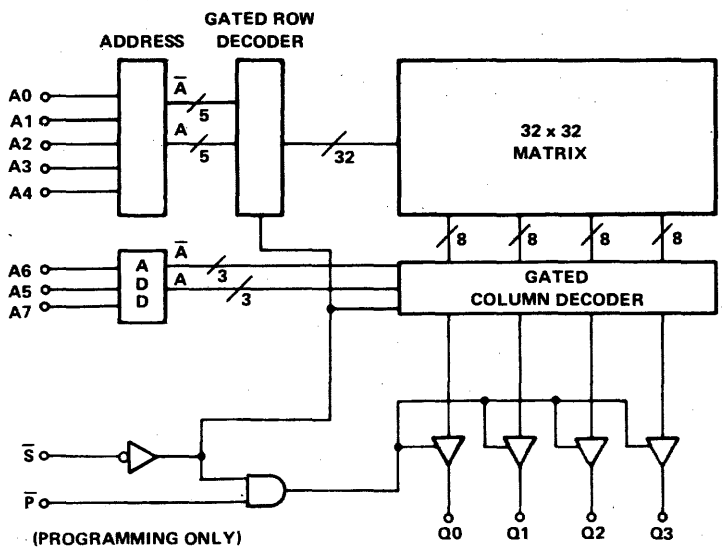
TOP VIEW



Logic Symbol

Description

The HM-6611 is a part of a family of fusible link CMOS PROMs featuring three state outputs. This device is static, TTL compatible, and has a 100 μA maximum standby current over temperature at a VCC of 5 volts. 10V and full military temperature devices are available. Chip Select ($\overline{S}$) is used to place the device in the standby state and also forces the outputs into the high impedance state when it is high. Program Enable ($\overline{P}$) is used only during programming, and must be connected to VCC in the system. Pinout is similar to Bipolar PROMs and is pin for pin replaceable with the HM-6562, a 256 x 4 CMOS RAM, if $\overline{P}$ is tied to VCC. This allows a single memory board design with any organization of RAM and PROM.

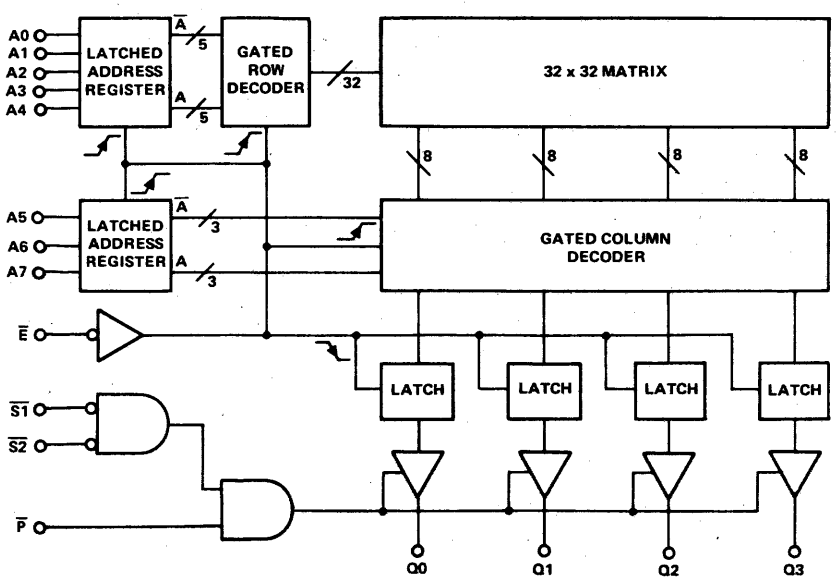
Logic Symbol



Description

The HM-6661 is a 256 x 4 static CMOS PROM fabricated using self-aligned silicon gate technology. Synchronous circuit techniques are employed to achieve high performance and low power operation.

On chip latches are provided for address and data outputs allowing efficient interfacing with microprocessor systems. The data output buffers can be forced to a high impedance state for use in expanded memory arrays.

The HM-6661 employs polysilicon fuses as static memory elements. It is also pin for pin replaceable with the HM-6561, a 256 x 4 CMOS RAM, if P is tied to VCC. This allows a single memory board design with any organization of RAM and PROM.

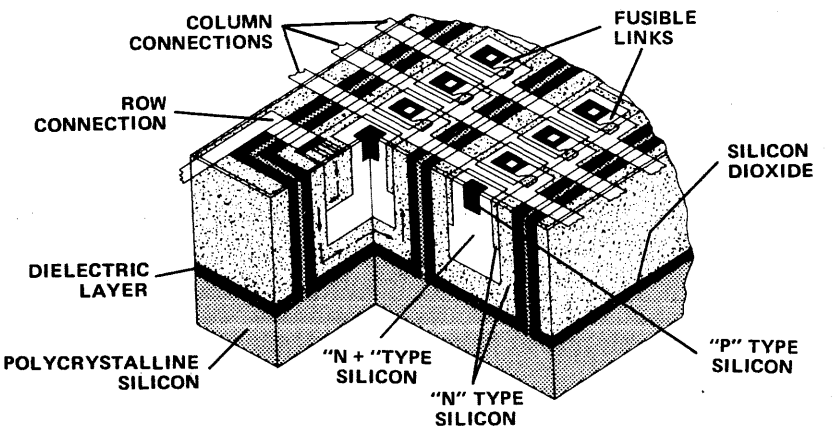
MONOLITHIC DIODE MATRICES

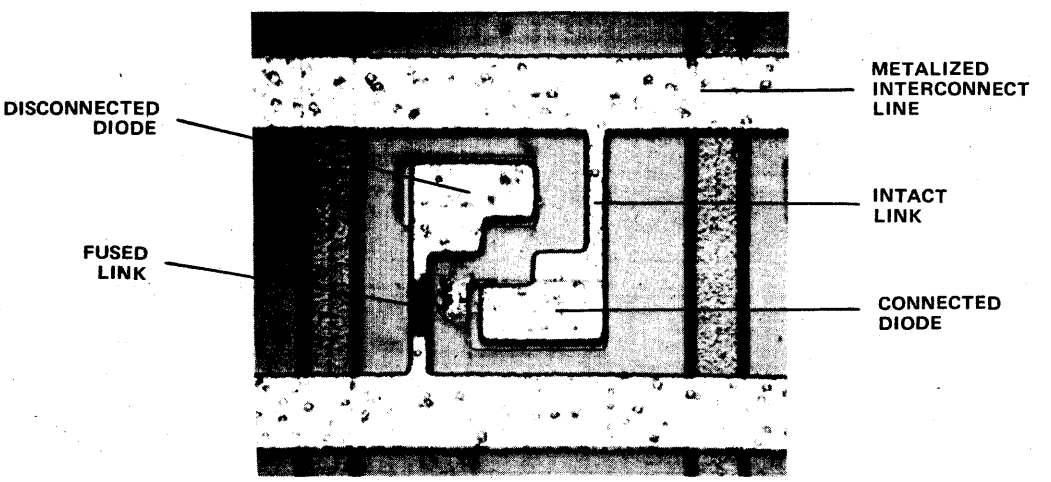
Features

- FIELD PROGRAMMABLE
- CMOS COMPATIBLE
- ZERO POWER DISSIPATION
- FAST SWITCHING
- FIVE POPULAR ORGANIZATIONS



Description

Designed with the CMOS circuit engineer in mind, these versatile diode matrices allow the application of logically powerful programmable solutions to low power CMOS system applications.



These devices incorporate an advanced dielectric isolation process to eliminate the need for power supply pins and allow parasitic free operation.

Programming is accomplished by cleanly vaporizing a fusible link by application of a brief high voltage pulse to a selected array element. This operation open circuits a row to column orring diode eliminating their former interaction.

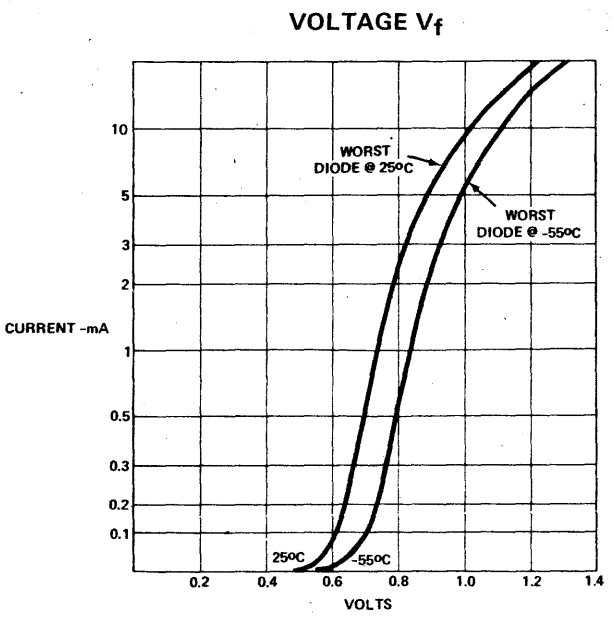
CUSTOM PATTERNS

When ordering a matrix with a custom pattern: Send a paper tape, or copy a matrix pattern and circle out those diodes to be removed from the matrix. Another method to clearly identify a pattern is to call out respective anode and cathode for each diode to be removed, by package pin number.

ABSOLUTE MAXIMUM RATINGS

Forward Current	100mA
Surge Current (100 μs Max.)	200mA
Total Ckt. Dissipation (Still Air)	450mW
Storage Temperature (Ambient)	-65°C to +150°C



Maximum Ratings are limiting values above which permanent damage may occur.

Leadless Carriers

Harris Semiconductor is offering four CMOS RAMs in 18 pin leadless carriers. Electrical specifications for these parts are identical to the equivalent product in the standard DIP package. Mechanical specifications for the 18 pin leadless carriers are shown below. For availability and additional information contact your nearest Harris Representative or Harris Sales Office.

All electrical grades of the following product types are available as stock items:

HM4-5618	1024 x 1	CMOS RAM	18 Pin
HM4-6561	256 x 4	CMOS RAM	18 Pin
HM4-6504	4096 x 1	CMOS RAM	18 Pin
HM4-6514	1024 x 4	CMOS RAM	18 Pin

The Package Code for Leadless Carriers is 4.

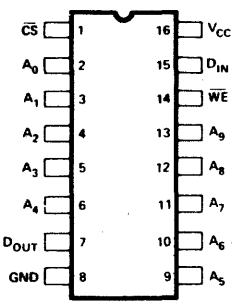
2115A, 2125A FAMILY
HIGH SPEED 1K X 1 BIT STATIC RAM

	2115AL 2125AL	2115A 2125A	2115AL-2 2125AL-2	2115A-2 2125A-2	M2115AL M2125AL	M2115A M2125A
Max. T_{AA} (ns)	45	45	70	70	75	55
Max. I_{CC} (mA)	75	125	75	125	75	125
Operating Temperature Range (°C)	0-70				−55 to +125	

- **Pin Compatible to 93415A And 93425A**
- **Fan-Out Of 10 TTL (2115A Family) -- 16mA Output Sink Current**
- **HMOS Technology - High Reliability**
- **Low Operating Power Dissipation --Max. 0.39mW/Bit (2115AL, 2125AL) -- Max. 0.41mW/Bit (M2115AL, M2125AL)**
- **TTL Inputs And Outputs**
- **Single + 5V Supply**
- **Uncommitted Collector And Three-State Output**
- **Standard 16-Pin Dual in-Line Package**

The Intel® 2115A and 2125A families are high-speed, 1024 words by 1 bit random access memories. Both open collector (2115A) and three-state output (2125A) are available. The 2115A and 2125A use fully DC stable (static) circuitry throughout — in both the array and the decoding and, therefore, require no clocks or refreshing to operate. The data is read out non-destructively and has the same polarity as the input data.

The 2115AL/2125AL at 45 ns maximum access time and the 2115AL-2/2125AL-2 at 70 ns maximum access time are fully compatible with the industry-produced 1K bipolar RAMs, yet offer a significant reduction in power of their bipolar equivalents. The power dissipation of the 2115AL/2125AL and 2115AL-2/2125AL-2 is 394 mW maximum. For systems already designed for 1K bipolar RAMs, the 2115A/2125A and the 2115A-2/2125A-2 at 45 ns and 70 ns maximum access times, respectively, offer complete compatibility with substantial reduction in maximum power dissipation.



The M2115AL and M2125AL are ideal for high-performance systems where speed and power dissipation are significant design considerations. They have a maximum access time of 75 ns, while power dissipation is only 413 mW maximum. The M2115A/M2125A at 55 ns maximum should be considered for applications in which speed is a primary design objective.

The devices are directly TTL compatible in all respects: inputs, outputs, and a single + 5V supply. A separate select ($\overline{CS}$) lead allows easy selection of an individual package when outputs are OR-tied.

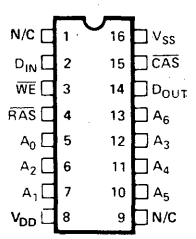
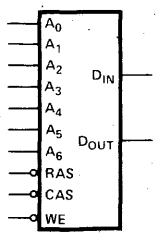
- **$\overline{RAS}$ Only Refresh**
- **128 Refresh Cycles Required Every 2ms**
- **Page Mode Capability**
- **$\overline{CAS}$ Controlled Output Allows Hidden Refresh**

The Intel® 2118 is a 16,384 word by 1-bit Dynamic MOS RAM designed to operate from a single +5V power supply. The 2118 is fabricated using HMOS — a production proven process for high performance, high reliability, and high storage density.



The 2118 uses a single transistor dynamic storage cell and advanced dynamic circuitry to achieve high speed with low power dissipation. The circuit design minimizes the current transients typical of dynamic RAM operation. These low current transients contribute to the high noise immunity of the 2118 in a system environment.

Multiplexing the 14 address bits into the 7 address input pins allows the 2118 to be packaged in the industry standard 16-pin DIP. The two 7-bit address words are latched into the 2118 by the two TTL clocks, Row Address Strobe ($\overline{RAS}$) and Column Address Strobe ($\overline{CAS}$). Non-critical timing requirements for $\overline{RAS}$ and $\overline{CAS}$ allow use of the address multiplexing technique while maintaining high performance.



The 2118 three-state output is controlled by $\overline{CAS}$, independent of $\overline{RAS}$. After a valid read or read-modify-write cycle, data is latched on the output by holding $\overline{CAS}$ low. The data out pin is returned to the high impedance state by returning $\overline{CAS}$ to a high state. The 2118 hidden refresh feature allows $\overline{CAS}$ to be held low to maintain latched data while $\overline{RAS}$ is used to execute $\overline{RAS}$-only refresh cycles.

The single transistor storage cell requires refreshing for data retention. Refreshing is accomplished by performing $\overline{RAS}$-only refresh cycles, hidden refresh cycles, or normal read or write cycles on the 128 address combinations of A_0 through A_6 during a 2ms period. A write cycle will refresh stored data on all bits of the selected row except the bit which is addressed.

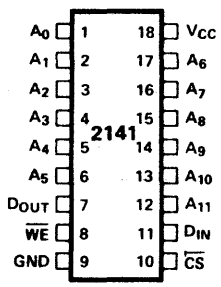
- **Completely Static Memory — No Clock or Timing Strobe Required**
- **Equal Access and Cycle Times**
- **Single +5V Supply**
- **Automatic Power-Down**
- **Directly TTL Compatible — All Inputs and Output**
- **Separate Data Input and Output**
- **Three-State Output**
- **High Density 18-Pin Package**

The Intel® 2141 is a 4096-bit static Random Access Memory organized as 4096 words by 1-bit using HMOS, a high-performance MOS technology. It uses a uniquely innovative design approach which provides the ease-of-use features associated with non-clocked static memories and the reduced standby power dissipation associated with clocked static memories. To the user this means low standby power dissipation without the need for clocks, address setup and hold times, nor reduced data rates due to cycle times that are longer than access times.



$\overline{CS}$ controls the power-down feature. In less than a cycle time after $\overline{CS}$ goes high — deselecting the 2141 — the part automatically reduces its power requirements and remains in this low power standby mode as long as $\overline{CS}$ remains high. This device feature results in system power savings as great as 85% in larger systems, where the majority of devices are de-selected.

The 2141 is placed in an 18-pin package configured with the industry standard pinout, the same as the 2147. It is directly TTL compatible in all respects: inputs, output, and a single +5V supply. The data is read out nondestructively and has the same polarity as the input data. A data input and a separate three-state output are used.

16384-BIT (16384-WORD BY 1-BIT) DYNAMIC RANDOM-ACCESS MEMORY

DESCRIPTION

The M5K 4116P and S are 16384-word by 1-bit dynamic RAMs, fabricated with the N-channel silicon-gate MOS process, and ideal for large-capacity memory systems where high speed, low power dissipation, and low costs are essential. The use of double-layer poly-silicon process technology and a single-transistor dynamic storage cell provide high circuit density at reduced costs, and the use of dynamic circuitry including sense amplifiers assures low power dissipation. Multiplexed address inputs permit both a reduction in pins to the standard 16-pin package configuration and an increase in system densities.

PIN CONFIGURATION (TOP VIEW)

Outline 16P1 (M5K4116P)
16S1 (M5K4116S)

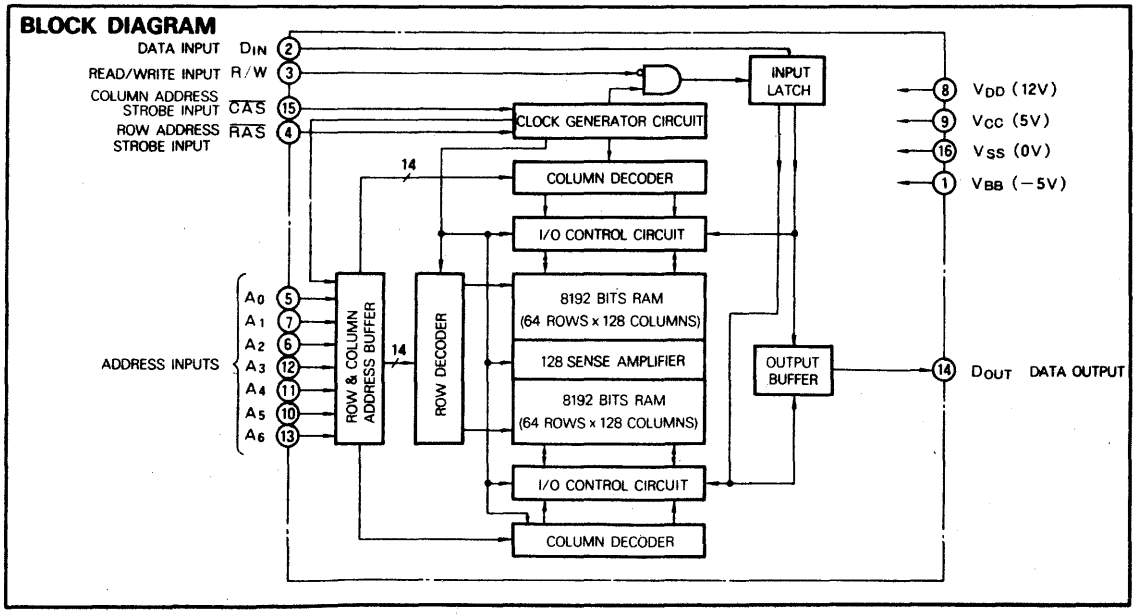
FEATURES

Type name	Access time (max) (ns)	Cycle time (min) (ns)	Power dissipation (typ) (mW)
M5K4116P, S-2	150	375	280
M5K4116P, S-3	200	375	280
M5K4116P, S-4	250	410	260

- Standard 16-pin package
- Voltage range on all power supplies (V_{DD}, V_{CC}, V_{BB}): ±10%
- Low standby power dissipation: 19.8mW (max)
- Low operating power dissipation: 462mW (max)
- Unlatched output enables two-dimensional chip selection and extended page boundary.
- Early-write operation gives common I/O capability.
- Read-modify-write, $\overline{RAS}$-only refresh, and page-mode capabilities
- All input terminals have low input capacitance and are directly TTL-compatible.
- Output is three-state and directly TTL-compatible
- 128 refresh cycles
- Interchangeable with Mostek's MK4116 in both electrical characteristics and pin configuration.

APPLICATION

- Main memory unit for computers



FUNCTION

The M5K 4116P and S provide, in addition to normal read, write, and read-modify-write operations, a number of other functions, e.g., page mode, $\overline{RAS}$-only refresh, and delayed-write. The input conditions for each are shown below.

Operation	Inputs						Output	Refresh	Remarks
	$\overline{RAS}$	$\overline{CAS}$	R/W	D_{IN}	Row address	Column address	D_{OUT}		
Read	ACT	ACT	NAC	DNC	APD	APD	VLD	YES	Page mode is identical except refresh is NO.
Write	ACT	ACT	ACT	VLD	APD	APD	OPN	YES	
Read-modify-write	ACT	ACT	ACT	VLD	APD	APD	VLD	YES	
$\overline{RAS}$-only refresh	ACT	NAC	DNC	DNC	APD	DNC	OPN	YES	
Standby	NAC	DNC	DNC	DNC	DNC	DNC	OPN	NO	

Note : ACT : active; NAC : nonactive; DNC : don't care; VLD : valid; APD : applied; OPN : open

16384-BIT (16384-WORD BY 1-BIT) DYNAMIC RANDOM-ACCESS MEMORY

SUMMARY OF OPERATIONS

Addressing

To select one of the 16384 memory cells in the M5K 4116P and S, the 14-bit address signal must be multiplexed into 7 address signals, which are then latched into the on-chip latch by two externally-applied clock pulses. First, the negative-going edge of the row-address-strobe pulse ($\overline{RAS}$) latches the 7 row-address bits; next, the negative-going edge of the column-address-strobe pulse ($\overline{CAS}$) latches the 7 column-address bits. Timing of the $\overline{RAS}$ and $\overline{CAS}$ clocks can be selected by either of the following two methods:

1. The delay time from $\overline{RAS}$ to $\overline{CAS}$ $t_{d(\overline{RAS}\text{-}\overline{CAS})}$ is set between the minimum and maximum values of the limits. In this case, the internal $\overline{CAS}$ control signals are inhibited almost until $t_{d(\overline{RAS}\text{-}\overline{CAS})max}$ ('gated $\overline{CAS}$' operation). The external $\overline{CAS}$ signal can be applied with a margin not affecting the on-chip circuit operations e.g. access time, and the address inputs can be easily changed from row address to column address.
2. The delay time $t_{d(\overline{RAS}\text{-}\overline{CAS})}$ is set larger than the maximum value of the limits. In this case the internal inhibition of $\overline{CAS}$ has already been released, so that the internal $\overline{CAS}$ control signals are controlled by the externally applied $\overline{CAS}$ which also controls the access time.

Data Input

Data to be written into a selected cell is strobed by the later of the two negative transitions of R/W input and $\overline{CAS}$ input. Thus when the R/W input makes its negative transition prior to $\overline{CAS}$ input (early write), the data input is strobed by $\overline{CAS}$, and the negative transition of $\overline{CAS}$ is set as the reference point for set-up and hold times. In the read-write or read-modify-write cycles, however, when the R/W input makes its negative transition after $\overline{CAS}$, the R/W negative transition is set as the reference point for set-up and hold times.

Data Output Control

The output of the M5K 4116P and S is in the high-impedance state when $\overline{CAS}$ is high. When the memory cycle in progress is a read, read-modify-write, or a delayed-write cycle, the data output will go from the high-impedance state to the active condition, and the data in the selected cell will be read. This data output will have the same polarity as the input data. Once the output has entered the active condition, this condition will be maintained until $\overline{CAS}$ goes high, irrespective of the condition of $\overline{RAS}$ (for a maximum of 10μs).

The output will remain in the high-impedance state throughout the entire cycle in an early-write cycle.

These output conditions, of the M5K 4116P and S, which can readily be changed by controlling the timing of the write pulse in a write cycle, and the width of the $\overline{CAS}$ pulse in a read cycle, offer capabilities for a number of applications, as follows.

1. Common I/O Operation

If all write operations are performed in the early-write mode, input and output can be connected directly to give a common I/O data bus.

2. Data Output Hold

The data output can be held between read cycles, without lengthening the cycle time, until the next cycle commences. This enables extremely flexible clock-timing settings for $\overline{RAS}$ and $\overline{CAS}$.

3. Two Methods of Chip Selection

Since the output is not latched, $\overline{CAS}$ is not required to keep the outputs of selected chips in the matrix in a high-impedance state. This means that $\overline{CAS}$ and/or $\overline{RAS}$ can both be decoded for chip selection.

4. Extended-Page Boundary

By decoding $\overline{CAS}$, the page boundary can be extended beyond the 128 column locations in a single chip. In this case, $\overline{RAS}$ must be applied to all devices.

Page-Mode Operation

This operation allows for multiple-column addressing at the same row address, and eliminates the power dissipation associated with the negative-going edge of $\overline{RAS}$, because once the row address has been strobed, $\overline{RAS}$ is maintained. Also, the time required to strobe in the row address for the second and subsequent cycles is eliminated, thereby decreasing the access and cycle times.

Refresh

The refreshing of the dynamic cell matrix is accomplished by performing a memory operation at each of the 128 row-address locations within a 2ms time interval. Any normal memory cycle will perform the refreshing, and $\overline{RAS}$-only refresh offers a significant reduction in operating power.

Power Dissipation

Most of the circuitry in the M5K 4116P and S is dynamic, and most of the power is dissipated when addresses are strobed. Both $\overline{RAS}$ and $\overline{CAS}$ are decoded and applied to the M5K 4116P and S as chip-select in the memory system, but if RAS is decoded, all unselected devices go into stand-by independent of the $\overline{CAS}$ condition, minimizing system power dissipation.

Power Supplies

Although the M5K 4116P and S require no particular power-supply sequencing so long as the devices are used within the limits of the absolute maximum ratings, it is recommended that the V_{BB} supply be applied first and removed last. V_{BB} should never be more positive than V_{SS} when power supply is applied to V_{DD}.

Some eight dummy cycles are necessary after power is applied to the device before memory operation is achieved.

4096-BIT(4096-WORD BY 1-BIT) STATIC RANDOM-ACCESS MEMORY

DESCRIPTION

The M5T 4044P series are 4096-word by 1-bit static RAMs, fabricated with the N-channel silicon-gate MOS process and designed for simple interfacing. They operate with a single 5V supply, as does TTL, and are directly TTL-compatible.

The members of the M5T 4044P series have three access time ranges; M5T 4044P-20, M5T 4044P-30, M5T 4044P-45.

FEATURES

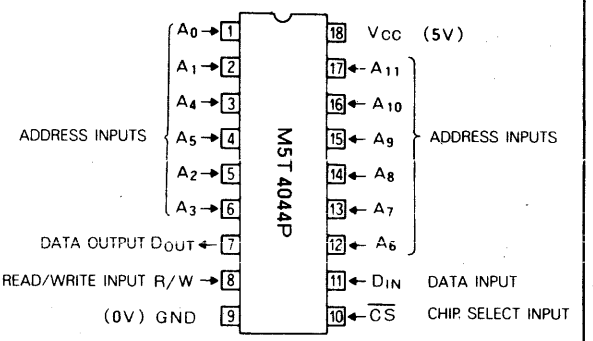
Parameter	M5T4044P-20	M5T4044P-30	M5T4044P-45
Access time (max)	200ns	300ns	450ns
Cycle time (min)	200ns	300ns	450ns

- Low power dissipation: 50μw/bit (typ)
- Single 5V supply
- Requires no clocks or refreshing
- All inputs and outputs are directly TTL-compatible
- All outputs are three-state and have OR-tie capability
- Simple memory expansion by chip-select ($\overline{CS}$) input
- Interchangeable with TI's TMS4044 in pin configuration and electrical characteristics

APPLICATION

- Small-capacity memory units

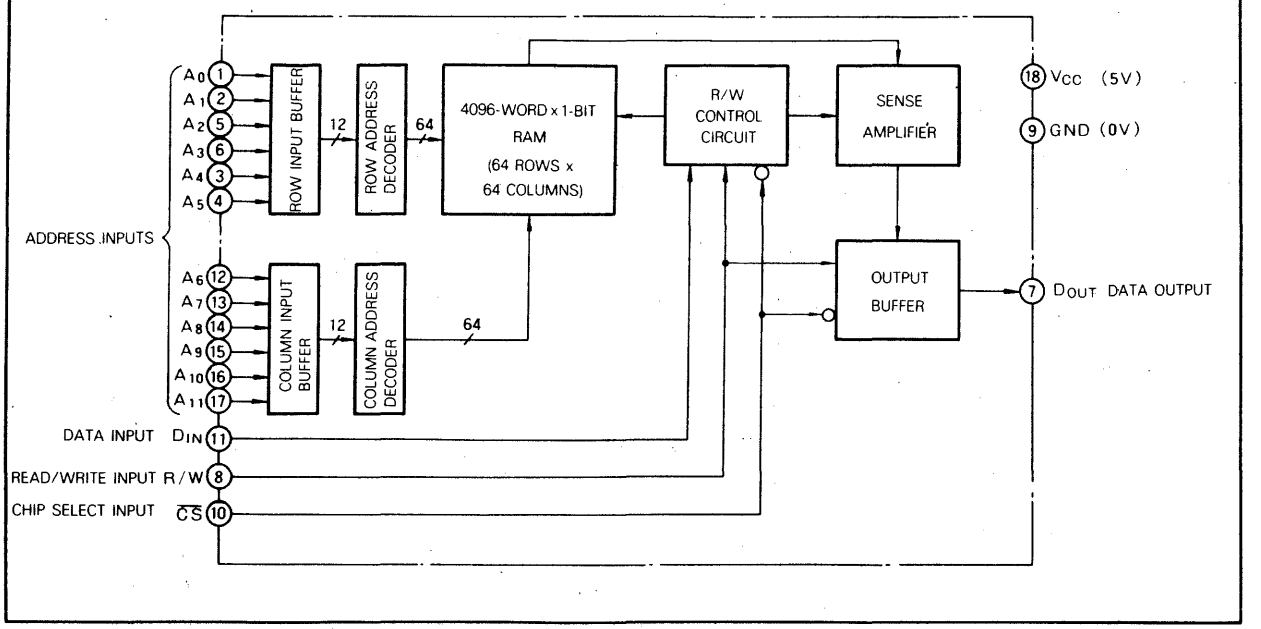
FUNCTION



The M5T 4044P series are very convenient to use, as they feature static circuits which require neither external clocks nor refreshing, and all inputs and outputs are directly compatible with TTL.

During a write cycle, when a location is designated by address signals $A_0 \sim A_{11}$ and the R/W signal goes low, the D_{IN} signal data at that time are written.

During a read cycle, when the R/W signal goes high and a location is designated by address signals $A_0 \sim A_{11}$, the data of the designated address appear at the D_{OUT} terminals.



When signal $\overline{CS}$ is high, the chip is in the non-selectable state, disabling both reading and writing. In this case the output is in the floating (high-impedance) state, useful for OR-ties with other output terminals.

M58981S-30,M58981S-45

4096-BIT (1024-WORD BY 4-BIT) CMOS STATIC RANDOM-ACCESS MEMORY

DESCRIPTION

The M58981S series consists of two 1024-word by 4-bit static RAMs fabricated with the silicon-gate CMOS process and designed for low power dissipation and easy application of battery back-up.

Each member of the series, while maintained in the chip non-select state by the chip-select signal $\overline{CS}$, consumes power only at the low value of 15μA (max) standby current and accordingly is especially suitable as a memory system for battery-operated applications and for battery back-up.

Each member operates on a single 5V supply, as does TTL, and inputs and outputs are directly TTL-compatible and are provided with common I/O terminals.

FEATURES

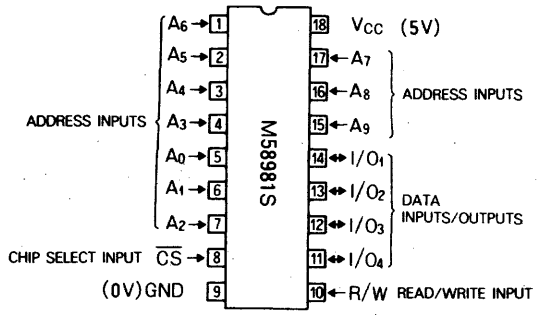
- Access time M58981S-30: 300ns (max)
  M58981S-45: 450ns (max)
- Low power dissipation in the standby mode: 15μA (max)
- Single 5V power supply
- Data holding at 2V supply voltage
- No external clock or refreshing operation required
- Both inputs and outputs are directly TTL-compatible
- Outputs are three-state, with OR-tie capability
- Simple memory expansion by chip-select signals
- Data terminals are common for both inputs and outputs
- Pin configuration is identical with those of Mitsubishi's M58724S (N-channel 4K static RAM), Intel's 2114, and TI's TMS4045.

APPLICATION

- Battery-driven or battery back-up small-capacity memory units

FUNCTIONS

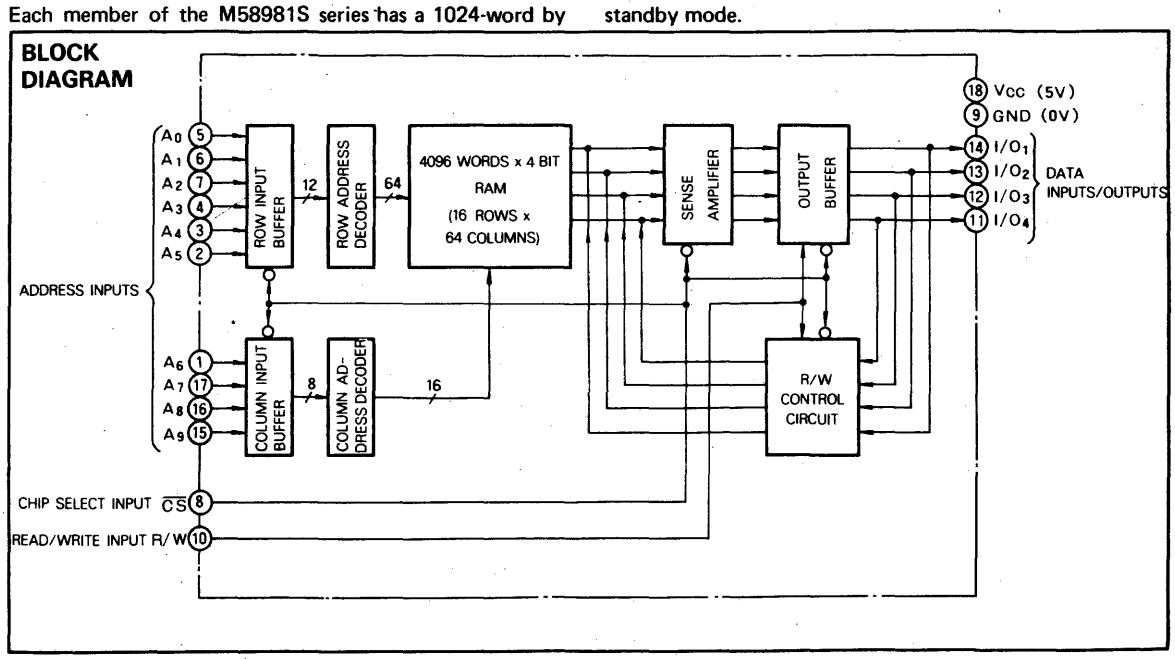
Each member of the M58981S series has a 1024-word by 4-bit organization and provides common data input and output terminals.



During a write cycle, when a location is designated by adress signals A_0~A_9 and signal R/W goes low, the data of the I/O at that time is written.

During a read cycle, when a location is designated by address signals A_0~A_9, and signal R/W goes high, the data of the designated address appears at the I/O terminals.

When signal $\overline{CS}$ is high, the chip is in the non-selectable state, disabling both reading and writing. In this case, the output is in the floating (high-impedance state) useful for OR-ties with the output terminals of other chips.



Also in the chip non-select state, the system operates with a low power dissipation, having a standby current of 15μA (max), so that the memory data can be held at a supply voltage of 2V, enabling battery back-up operation during power failure and power-down operation in the standby mode.

M5L 2114LP, M5L 2114LP-2, M5L 2114LP-3

4096-BIT(1024-WORD BY 4-BIT) STATIC RANDOM-ACCESS MEMORY

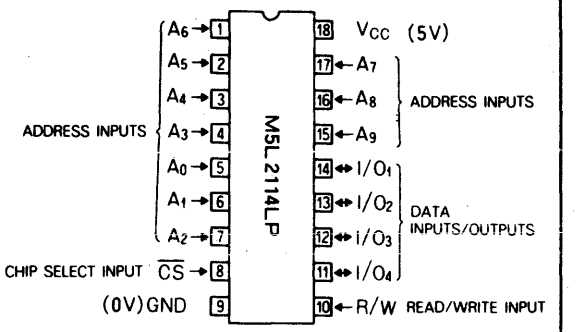
DESCRIPTION

The M5L 2114LP series are 4096-bit static random-access memories organized as 1024 words of 4 bits and designed for simple interfacing. They are fabricated using N-channel silicon-gate MOS technology. They operate with a single 5V supply, as does TTL, and the inputs and outputs are directly TTL compatible. I/O terminals are common. The M5L 2114LP series has three access time ranges; M5L 2114LP, M5L 2114LP-2 and M5L 2114LP-3.

FEATURES

Parameter	M5L 2114LP-2	M5L 2114LP-3	M5L 2114LP
Access time (max)	200ns	300ns	450ns
Cycle time (min)	200ns	300ns	450ns

- Low power dissipation: 50μw/bit (typ)
- Single 5V supply voltage
- Requires neither external clock nor refreshing
- All inputs and outputs are directly TTL compatible
- All outputs are three-state, with OR-tie capability
- Easy memory expansion by chip-select ($\overline{CS}$) input
- Common data I/O terminals
- Interchangeable with Intel's 2114L and TI's TMS4045 in pin configuration and electrical characteristics.



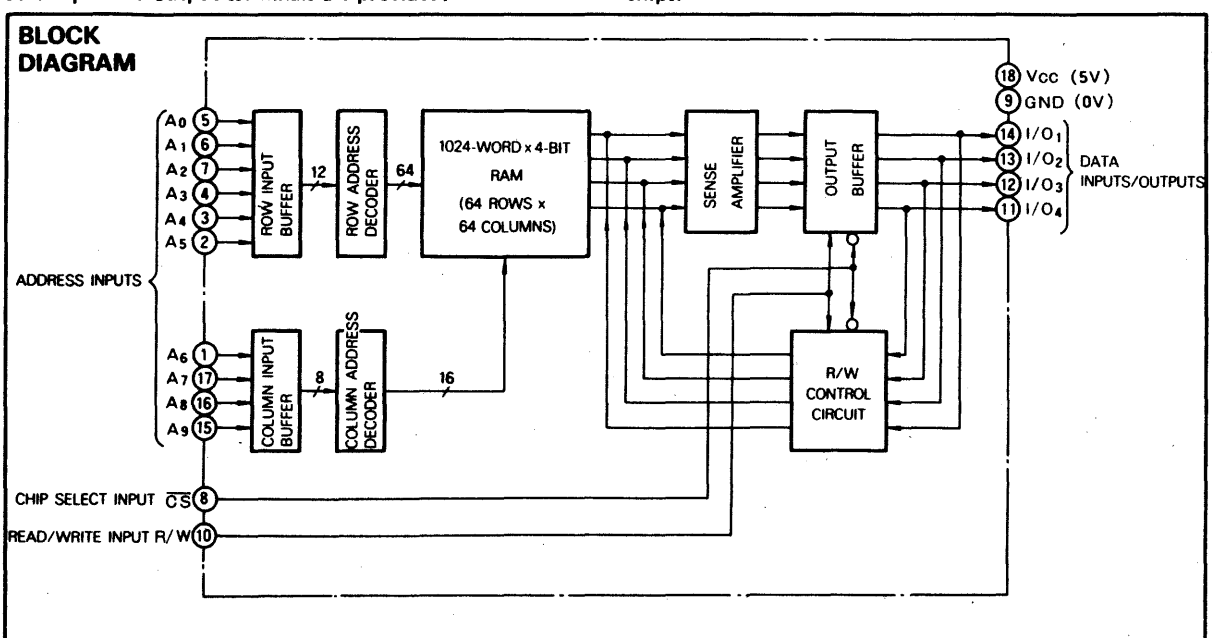
APPLICATION

- Small-capacity memory units

FUNCTION

The M5L 2114LP series operate with a single 5V power supply, and the inputs and outputs are directly compatible with TTL. All circuits are completely static, rendering external clock and refresh operations unnecessary, and making the members of the series extremely easy to use. Common data input and output terminals are provided.

PIN CONFIGURATION (TOP VIEW)



Outline 18P1

During a write cycle, when a location is designated by address signals $A_0 \sim A_9$ and the R/W signal goes low, the data at the I/O terminals are written.

During a read cycle, when the R/W signal goes high and a location is designated by address signals $A_0 \sim A_9$, the data of the designated address appear at the I/O terminals.

When signal $\overline{CS}$ is high, the chip is in the non-selectable state, disabling both reading and writing. In this case the data outputs are in the floating (high-impedance) state, useful for OR-ties with the output terminals of other chips.

M5L 2708S, M5L 2708S-65

8192-BIT (1024-WORD BY 8-BIT) ERASABLE AND ELECTRICALLY REPROGRAMMABLE ROM

DESCRIPTION

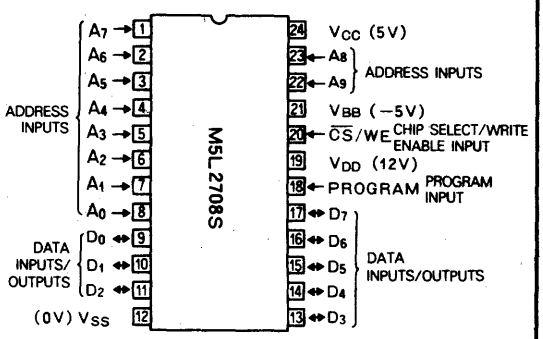
The M5L 2708S and M5L 2708S-65 are FAMOS (floating-gate avalanche-injection MOS) ultraviolet-light erasable and electrically reprogrammable 8192-bit (1024-word by 8-bit) EPROMs. They incorporate N-channel silicon-gate MOS technology, are designed for microcomputer system applications, and have direct TTL-compatibility for all inputs and outputs, without extra interface circuits.

FEATURES

- Fast programming: 100s/8192 bits (typ)
- Access time:
  - M5L 2708S: 450ns (max)
  - M5L 2708S-65: 650ns (max)
- Low power dissipation during programming
- No clocks required; the circuitry is entirely static
- Data inputs and outputs TTL-compatible during read and program modes
- Easy memory expansion by chip-select/write-enable ($\overline{CS}$/WE) input
- Typical power supply voltages: 12V, 5V, −5V
- For large volume production; pin compatible with the Mitsubishi M58730-XXXS mask ROM
- Interchangeable with Intel's 2708 in pin configuration and electrical characteristics

APPLICATION

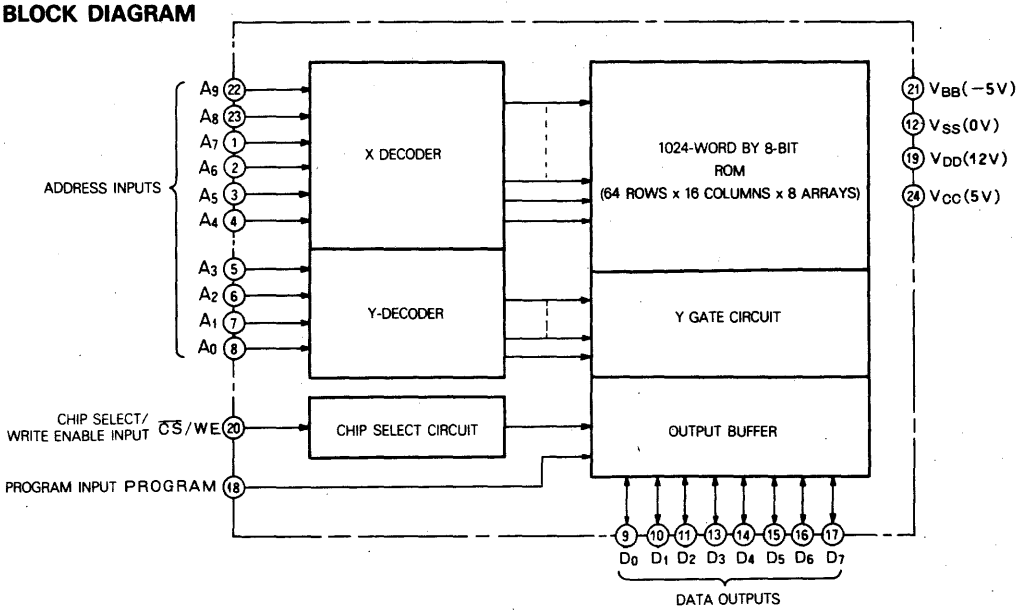
- Computers and peripheral equipment



FUNCTION

Read—Set the $\overline{CS}$/WE terminal to the read mode (0~5V). Low-level input to $\overline{CS}$/WE and address signals to the address input ($A_0 \sim A_9$), make the data contents of the designated address location available at the data inputs/outputs ($D_0 \sim D_7$). When the $\overline{CS}$/WE signal is high, data inputs/outputs ($D_0 \sim D_7$) are in a floating state.

Write—Set the $\overline{CS}$/WE terminal to the write mode (12V). A program pulse will effect the write operation for the data at each address loaded via data inputs/outputs ($D_0 \sim D_7$). For details refer to the description of the programming mode.



Erase—Erase is effected by exposure to ultraviolet light through the transparent window.

PIN CONFIGURATION (TOP VIEW)

M5L 2708S, M5L 2708S-65

8192-BIT (1024-WORD BY 8-BIT) ERASABLE AND ELECTRICALLY REPROGRAMMABLE ROM

FUNCTIONAL OPERATIONS

Programming Procedure

The M5L 2708S, S-65 are in the '1' state (with high-level output) after erase, and go into the '0' state (with low-level output) after programming. All bits of the M5L 2708S, S-65 are initially in the '1' state, and must be programmed according to the following procedures.

The chip enters the program mode when 12V is supplied to the $\overline{CS}$/WE input (pin 20). Data to be programmed are presented, 8 bits in parallel, to the data inputs/outputs ($D_0 \sim D_7$) and the addresses are set up by the address inputs. After address and data set-up, one program pulse is applied to the program input (pin 18) for each address from 0 to 1023. This pass through all addresses, known as a program loop, must be repeated a number of times, N, which depends upon the width of the program pulse and must satisfy the condition $N \cdot t_{W(P)} \geqq 100ms$.

Erase Procedure

The M5L 2708S, S-65 can be erased by exposure to high-intensity short-wave ultraviolet light at a wavelength of 2537Å through the transparent lid provided. The required exposure is approximately $15Ws/cm^2$. If the energy of the lamp used is unknown, find the total time (t_E) required to erase all bits and use a short-wave ultraviolet-light exposure time of 3 to 5 times this value.

HANDLING PRECAUTIONS FOR FAMOS DEVICES

In addition to general handling precautions for MOS devices, the following points apply to FAMOS devices.

1. High voltages are used when programming, and the conditions under which it is performed must be carefully controlled to prevent the application of excessively high voltages.
2. Before erasing, clean the surface of the transparent lid to remove completely oily impurities, which may impede irradiation and affect the erasing characteristics.
3 This ultraviolet-light erasable PROM is erasable by ultraviolet-light with wavelengths under 4,000Å. For use involving long exposure to direct sunlight or to lamps radiating at these wavelengths, the transparent window should be covered with opaque tape.

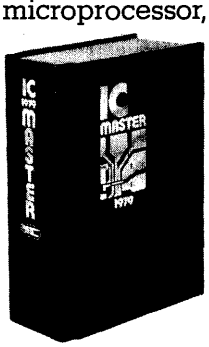
"I need to know if this device exists, and if there are any alternate sources. Where do I start?"

- Memory IC
- RAM
- Static
- 1024x1
- CMOS
- 250 Nanoseconds
- 5 Volts

If you're spending hours to solve a problem similar to the one above, you're behind the times...



It only takes a few seconds with "THE MASTER."

Clear your desk for action with the newly revised 1979 IC Master. Its all-under-one-cover features include: Over 40,000 standard products from more than 87 different companies. . . five different selection guides (memory, microprocessor, interface, linear and digital.) . . . alternate source directory for pin- for- pin, function- for- function replacements . . . applications directory. . . complete military section . . . a complete part numbering guide . . . etc.

You don't have to search through stacks of catalogs. Simply look up the specs and function you need. You don't need a part number to start with.

All you need is a problem to use The Master. Does the device exist? Who makes it? Is there an alternate source? What's the part number? Is there an applications note? Who is my closest distributor—etc.

Standard Performance Schottky Generic PROM Family 53/63XX-1

Features/Benefits

- Standard Schottky processing
- Reliability proven nichrome fusible links (qualified for MIL-M-38510)
- Drop in compatible ROMs
- PNP inputs for low input current
- Compatible pin configurations for upward expansion
- 4-bit-wide and 8-bit-wide for byte oriented applications

Application

- Microprogram instruction
- Microprocessor program store
- Look up table
- Character generator
- Random logic
- Code converter

Description

The 53/63XX-1-series generic PROM family offers the widest selection of sizes and organizations available in the industry. The 4-bit-wide PROMs range from 256x4 to 1024x4 and feature upward/downward pin out compatibility in the space saving 16 and 18 pin packages. The 8-bit-wide PROMs range from 32x8 to 1024x8 in a wide selection of package sizes. All PROMs have the same programming specifications allowing a single generic programmer.

The family features low input current PNP inputs, full Schottky clamping and three-state and open collector outputs. The nichrome fuses store a logical high and are programmed to the low state. Special on chip circuitry and extra fuses provide preprogramming tests which assure high programming yields and high reliability.

The 63 series is specified for operation over the commercial temperature and voltage range. The 53 series is specified for the military ranges.

High Performance Schottky Generic PROM Family 53/63SXXX

Features/Benefits

- **Highest speed Schottky PROM family available**
- **Advanced Schottky processing**
- **Pin compatible with standard Schottky PROMs and ROMs, 53/63XX-1, 52/62XX-1**
- **PNP inputs for low input current**
- **Compatible pin configurations for upward expansion**
- **4-bit-wide and 8-bit-wide for byte oriented applications**

Applications

- **Microprogram control store**
- **Microprocessor program store**
- **Look up table**
- **Character generator**
- **Random logic**
- **Code converter**

Description

The 53/63SXXX series generic PROM family offers the fastest and widest selection of sizes and organizations available in the industry. The 4-bit-wide PROMs range from 256x4 to 4096x4 and feature upward/downward pin out compatibility in the space saving 16, 18 and 20 pin packages. The 8-bit-wide PROMs range from 32x8 to 2048x8 in a wide selection of package sizes. All PROMs have the same programming specifications allowing a single generic programmer.

The family features low input current PNP inputs, full Schottky clamping and three-state and open collector outputs. The titanium-tungsten fuses store a logical low and are programmed to the high state. Special on chip circuitry and extra fuses provide pre-programming testing which assure high programming yields and high reliability.

The 63 series is specified for operation over the commercial temperature and voltage range. The 53 series is specified for the military ranges.

MMI Part Numbering System

The new system approaches part numbering using the method of keying important attributes of the device. The military/commercial and PROM/ROM numbering system is preserved i.e., 5/6 - 3/2. These two digits are separated from the actual device number by a technology/configuration designator using letters.

"S" = Schottky
"LS" = Low Power Schottky
"PS" = Power Switched
"RA" = Registered Asynchronous
"RS" = Registered Synchronous

The number following this code describes....

1. The size of the memory (bits)
2. The memory organization by specifying the number of outputs
3. Output configuration and pin out/package options

If a higher performance part co-exists i.e., faster speed, then a suffix letter (A) is added to distinguish between the two devices. The normal package letter designator follows last as is custom.

High Performance Low Power Schottky Generic PROM Family 53/63LSXXX

Features/Benefits

- **Largest generic low power Schottky PROM family available**
- **Advanced Schottky processing using ion implanted for low power and high speed**
- **Pin compatible with standard Schottky PROMs and ROMs, 53/63XX-1, 52/62XX-1**
- **PNP inputs for low input current**
- **Compatible pin configurations for upward expansion**
- **4-bit-wide and 8-bit-wide for byte oriented applications**

Applications

- **Microprogram control store**
- **Microprocessor program store**
- **Look up table**
- **Character generator**
- **Random logic**
- **Code converter**

Description

The 53/63LSXXX series generic PROM family offers the lowest power and fastest speeds available in the industry. The 4-bit-wide PROMs range from 256x4 to 2048x4 and feature upward/downward pin out compatibility in the space saving 16 and 18 pin packages. The 32x8 PROM is also included in our low power Schottky family and a typical access time of 24 ns makes it a natural programmable logic element choice. Other 8-bit- wide PROMs are available up to 2048x8. All PROMs have the same programming specifications allowing a single generic programmer.

The family features low input current PNP inputs, full Schottky clamping and three-state and open collector outputs. The titanium-tungsten fuses store a logical low and are programmed to the high state. Special on chip circuitry and extra fuses provide pre-programming testing which assure programming yields and high reliability.

The 63 series is specified for operation over the commercial temperature and voltage range. The 53 series is specified for the military range.

High Performance Registered Schottky—4-Bit-Wide Generic PROM Family
53/63RAXXX, 53/63RSXXX

Features/Benefits
- **Largest generic PROM family available incorporating edge triggered "D" registers.**
- **Advanced Schottky processing.**
- **4-bit-wide in 18 and 20 pin Skinny DIPs™ for high board density.**
- **Synchronous enable allow easy busing of outputs for word expansion.**
- **Lower system package counts.**
- **Lower system power.**
- **Faster cycle times.**
- **25ns clock to output and 40ns address set-up times guaranteed over commercial specification.**
- **24mA I_{OL} output drive capability.**

Applications
- **Pipelined microprogramming**
- **State sequencers**
- **Next address generation**
- **Mapping PROM**

Description
A family of registered PROMs offers new savings for designers of pipelined microprogrammable systems. The wide instruction register, which holds the microinstruction during execution, is now incorporated into the PROM chip.

Edge Triggered Register
The PROM output is loaded into a 4-bit register on the rising edge of the clock. The use of the term "register" is to be distinguished from the term "latch," in that a register contains master slave flip-flops and the latch contains gated flip-flops. The advantages of using a register are that system timing is simplified, and faster micro cycle times can be obtained.

The output of the register is buffered by three-state drivers which are compatible with the new low-power Schottky three-state bus standard, i.e., I_{OL} is 24mA at V_{OL} of 0.5V.

The 4-bit-wide family in 18-pin and 20-pin packages feature either synchronous or asynchronous enables the synchronous enables and upwards pin compatibility. The synchronous enable powers up in the high impedance state and is used when more than one registered PROM is bused together to increase word length. All devices are specified over both commercial and military temperature ranges.

Standard Performance Schottky Generic ROM Family

52/62XX-1, 52/62XX-2

Features/Benefits

- Largest generic ROM family available
- PNP inputs for low input current
- Compatible pin configurations for upward expansions
- 4-bit-wide and 8-bit-wide for byte oriented applications
- Bit density from 256 to 16384
- Interchangeable PROM compatibility
- High speed Schottky technology

Applications

- High speed for microprogrammed applications
- Microprocessor program store
- Look up table
- Character generator
- Random logic
- Code converter

Description

The 52/6200-series generic ROM family offers the widest selection of sizes and organizations available in the industry. The 4-bit-wide ROMs range from 256x4 to 1024x4 and feature upward/downward pinout compatibility in the space saving 16 and 18 pin packages. The 8-bit-wide ROMs range from 32x8 to 2048x8 in a wide selection of package sizes. Additional 5-bit, 9-bit and 10-bit-wide output configurations are available for your custom logic or character generator applications.

The family features low input current PNP inputs, full Schottky clamping and three-state and open collector outputs.

The 62 series is specified for operation over the commercial temperature and voltage range. The 52 series is specified for the military ranges. 52XX-2 and 62XX-2 devices offer enhanced speed specifications.

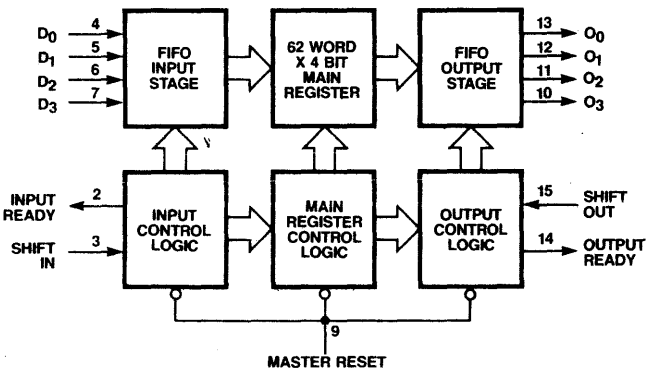
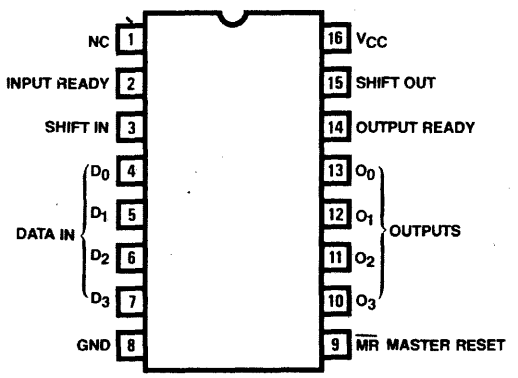
First-In First-Out (FIFO) 64x4 Serial Memory

57401/67401



Features/Benefits

- 12 MHz shift in, shift out typical rates
- Advanced Schottky bipolar processing
- TTL inputs and outputs
- Readily expandable in word and bit dimensions
- Asynchronous or synchronous operation
- Pin compatible with Fairchild's F3341 MOS FIFO and ten times as fast



Description

The 57401 is an expandable "fall-through" high speed First-In First-Out (FIFO) memory organized 64 words by 4-bit. A 12 MHz data rate allows usage in high speed tape or disc controllers and communication buffer applications. The 67401 is specified over the commercial operating range 0 –75°C and the 57401 is specified over the military operating of –55°C to +125°C.

NOTES: 1. This parameter defines total time from the time data is present at D_0-D_3 to the time it is available at O_0-O_3 with FIFO initially empty and total time from the time data is extracted from O_0-O_3 to IR High with FIFO initially full.
2. Master Reset clears the 57401/67401 to the all cells empty state.

MMI

MEMORY

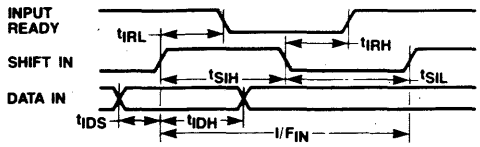
Functional Description

Data Input

Data is entered into the FIFO on D_0-D_3 inputs. To enter data the Input Ready (IR) output should be HIGH, indicating that the first location is ready to accept data. Data then present at the four data inputs is entered into the first location when the Shift In (SI) is brought HIGH. A SI HIGH signal causes the RI to go LOW. Data remains at the first location until SI is brought LOW. When SI is brought LOW and the FIFO is not full, IR will go HIGH, indicating that more room is available. Simultaneously, data will propagate to the second location and continue shifting until it reaches the output stage or a full location. If the memory is full, IR will remain LOW.

Data Transfer

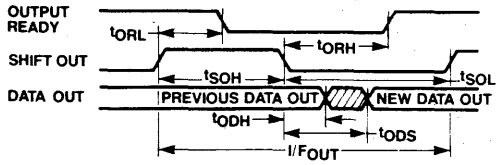
Once data is entered into the second cell, the transfer of any full cell to the adjacent (downstream) empty cell is automatic, activated by an on-chip control. Thus data will stack up at the end of the device while empty locations will "bubble" to the front. t_{PT} defines the time required for the first data to travel from input to the output of a previously empty device.



Data Output

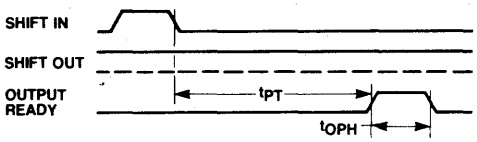
Data is read from the O_0-O_3 outputs. When data is shifted to the output stage, Output Ready (OR) goes HIGH, indicating the presence of valid data. When the OR is HIGH, data may be shifted out by bringing the Shift Out (SO) HIGH. A HIGH signal at SO causes the OR to go LOW. Valid data is maintained while the SO is HIGH. When SO is brought LOW the upstream data, provided that stage has valid data, is shifted to the output stage. When new valid data is shifted to the output stage, OR goes HIGH. If the memory is emptied, OR stays LOW.

Input Ready and Output Ready may also be used as status signals indicating that the FIFO is completely full (Input Ready stays LOW for at least t_{PT}) or completely empty (Output Ready stays LOW for at least t_{PT}).



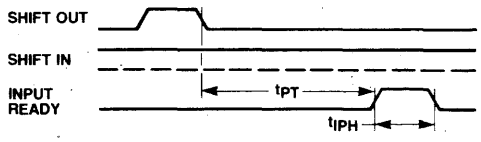
©IC MASTER 1979

Timing Diagrams



1. Input data must remain stable during t_{IDS} and t_{IDH}.
2. Input Ready HIGH indicates that space is available and a Shift In pulse may be applied. Input Ready LOW indicates that the FIFO is full or that a previous Shift In operation is not complete. Shift In pulses applied while Input Ready is LOW will be ignored.
3. The rise of Input Ready indicates that the data at the D0-D3 inputs has been accepted and that the input stage is empty.

Figure 1. FIFO Input Timing



1. Output data will be stable at the rise of Output Ready.
2. Output Ready HIGH indicates that data is available and a Shift Out pulse may be applied. Output Ready LOW indicates that the FIFO is empty or that a previous Shift Out operation is still in progress. Shift Out pulses applied while Shift Out Ready is LOW will be ignored.
3. The rise of Output Ready indicates that new data has been loaded into the output stage.

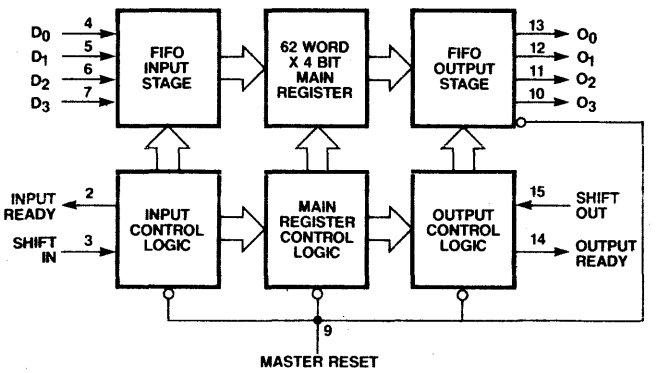
First-In First-Out (FIFOs) 64x4, 64x5 Serial Memories

57401A/67401A, 57402A/67402A

Features/Benefits

- 15 MHz shift in, shift out typical rates
- Advanced Schottky bipolar processing
- TTL inputs and outputs
- Readily expandable in word and bit dimensions
- Asynchronous or synchronous operation
- 64x4 FIFO pin compatible with Fairchild's F3341 MOS FIFO and ten times as fast
- 4 & 5-bit organizations for 9 bit expansion
- Master reset clears outputs to zero state

Description



The 57401A/402A are expandable "fall-through" high speed First-In First-Out (FIFO) memories. The 57401A is organized 64 words by 4-bits. The 57402A is organized 64 words by 5-bits. A 15 MHz data rate allows usage in high speed tape or disc controllers and communication buffer applications. The 67401A/67402A is specified over the commercial operating range 0−75°C and the 57401A/57402A is specified over the military operating range of −55°C to +125°C.

Functional Description

Data Input

Data is entered into the FIFO on Dn inputs. To enter data the Input Ready (IR) output should be HIGH, indicating that the first location is ready to accept data. Data then present at the data inputs is entered into the first location when the Shift In (SI) is brought HIGH. A SI HIGH signal causes the RI to go LOW. Data remains at the first location until SI is brought LOW. When SI is brought LOW and the FIFO is not full, IR will go HIGH, indicating that more room is available. Simultaneously, data will propagate to the second location and continue shifting until it reaches the output stage or a full location. If the memory is full, it will remain LOW.

Data Transfer

Once data is entered into the second cell, the transfer of any full cell to the adjacent (downstream) empty cell is automatic, activated by an on-chip control. Thus data will stack up at the end of the device while empty locations will "bubble" to the front. t_{PT} defines the time required for the first data to travel from input to the output of a previously empty device.

Data Output

Data is read from the On outputs. When data is shifted to the output stage, Output Ready (OR) goes HIGH, indicating the presence of valid data. When the OR is HIGH, data may be shifted out by bringing the Shift Out (SO) HIGH. A HIGH signal at SO causes the OR to go LOW. Valid data is maintained while the SO is HIGH. When SO is brought LOW the upstream data, provided that stage has valid data, is shifted to the output stage. When new valid data is shifted to the output stage, OR goes HIGH. If the memory is emptied, OR stays LOW.

Input Ready and Output Ready may also be used as status signals indicating that the FIFO is completely full (Input Ready stays LOW for at least t_{PT}) or completely empty (Output Ready stays LOW for at least t_{PT}).

Programmable Array Logic Family

PAL™ Series 20 Data Sheet

Patent Allowed

Features/Benefits

- **Programmable replacement for conventional TTL logic.**
- **Reduces IC inventories substantially and simplifies their control.**
- **Reduces chip count by 4 to 1.**
- **Expedites and simplifies prototyping and board layout.**
- **Saves space with 20-pin Skinny DIP packages.**
- **High speed: 25ns typical propagation delay.**
- **Programmed on standard PROM programmers.**
- **Programmable three-state outputs.**
- **Special feature reduces possibility of copying by competitors.**

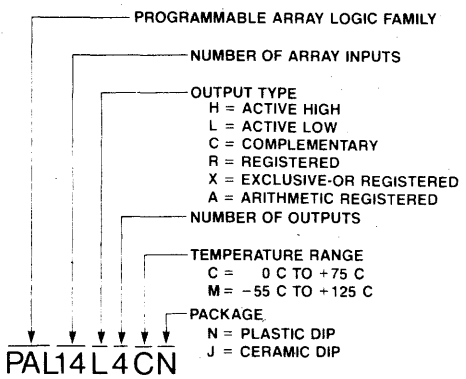
Description

The PAL family utilizes an advanced Schottky TTL process and the Bipolar PROM fusible link technology to provide user programmable logic for replacing conventional SSI/MSI gates and flip-flops at reduced chip count.

The family lets the systems engineer "design his own chip" by blowing fusible links to configure AND and OR gates to perform his desired logic function. Complex interconnections which previously required time-consuming layout are thus "lifted" from PC board etch and placed on silicon where they can be easily modified during prototype check-out or production.

The PAL transfer function is the familiar sum of products. Like the PROM, the PAL has a single array of fusible links. Unlike the PROM, the PAL is a programmable AND array driving a fixed OR array (the PROM is a fixed AND array driving a programmable OR array). In addition the PAL provides these options:

- Variable input/output pin ratio
- Programmable three-state outputs
- Registers with feedback
- Arithmetic capability



TM PAL is a Trade Mark of Monolithic Memories

Unused inputs are tied directly to V_{CC} or GND. Product terms with all fuses blown assume the logical high state, and product terms connected to both true and complement of any single input assume the logical low state. Registers consist of D type flip-flops which are loaded on the low to high transition of the clock. All registers are designed to power up to logical high state at the output pin. PAL Logic Diagrams are shown with all fuses blown, enabling the designer use of the diagrams as coding sheets. 8½ x 11 Logic Diagrams are available on request.

The entire PAL family is programmed on inexpensive conventional PROM programmers with appropriate personality and socket adapter cards. Once the PAL is programmed and verified, two additional fuses may be blown to defeat verification. This feature gives the user a proprietary circuit which is very difficult to copy.

Programming

PAL fuses are programmed using a low-voltage linear-select procedure which is common to all 15 PAL types. The array is divided into two groups, products 0 thru 31 and products 32 thru 63, for which pin identifications are shown in Figure 1. To program a particular fuse, both an input line and a product line are selected according to the following procedure:

Step 1 Raise Output Disable, OD, to V_{IHH}

Step 2 Select an input line by specifying I_0, I_1, I_2, I_3, I_4, I_5, I_6, I_7 and L/R as shown in Table 1

Step 3 Select a product line by specifying A_0, A_1 and A_2 one-of-eight select as shown in Table 2

Step 4 Raise V_{CC} (pin 20) to V_{IHH}

Step 5 Program the fuse by pulsing the output pins, O, of the selected product group to V_{IHH} as shown in Table 2.

Step 6 Lower V_{CC} (pin 20) to 6.0 V

Step 7 Pulse the CLOCK pin and verify the output pin, O, to be Low for active Low PAL types or High for active High PAL types.

Step 8 Lower V_{CC} (pin 20) to 4.2 V and repeat step 7

Step 9 Should the output not verify, repeat steps 1 thru 8 up to five (5) times.

This procedure is repeated for all fuses to be blown (see programming waveforms).

To prevent further verification, two last fuses may be blown by raising pin 1 and pin 11 to VP. VCC is not required during this operation.

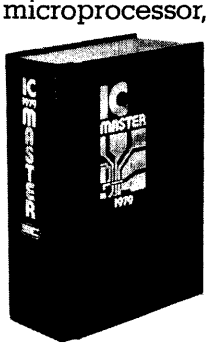
"I need to know if this device exists, and if there are any alternate sources. Where do I start?"

- Memory IC
- RAM
- Static
- 1024x1
- CMOS
- 250 Nanoseconds
- 5 Volts

If you're spending hours to solve a problem similar to the one above, you're behind the times...



It only takes a few seconds with "THE MASTER."

Clear your desk for action with the newly revised 1979 IC Master. Its all-under-one-cover features include: Over 40,000 standard products from more than 87 different companies... five different selection guides (memory, microprocessor, interface, linear and digital.) ... alternate source directory for pin- for- pin, function- for- function replacements ... applications directory... complete military section ... a complete part numbering guide ... etc.

You don't have to search through stacks of catalogs. Simply look up the specs and function you need. You don't need a part number to start with.

All you need is a problem to use The Master. Does the device exist? Who makes it? Is there an alternate source? What's the part number? Is there an applications note? Who is my closest distributor—etc.

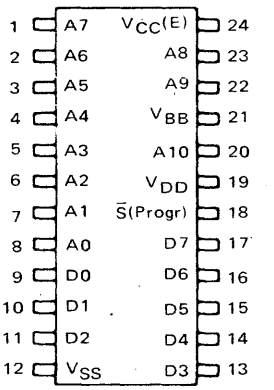
2048 × 8-BIT
UV ERASABLE PROM

2048 × 8 ERASABLE PROM



The TMS2716L and TMS27A16L are 16,384-bit Erasable and Electrically Reprogrammable PROMs designed for system debug usage and similar applications requiring nonvolatile memory that could be reprogrammed periodically. The transparent lid on the package allows the memory content to be erased with ultraviolet light. The TMS2716 is pin compatible with 2708 EPROMs, allowing easy memory size doubling.

- Organized as 2048 Bytes of 8 Bits
- Fully Static Operation (No Clocks, No Refresh)
- Standard Power Supplies of +12 V, +5 V, and −5 V
- Maximum Access Time = 300 ns — TMS27A16L
  450 ns — TMS2716L
- Chip-Select Input for Memory Expansion
- TTL Compatible — No Pull-up Resistors Required
- Three-State Outputs for OR-Tie Capability
- The TMS2716L is Pin Compatible to MCM2708L, MCM2708P, MCM2708C, and MCM68708L EPROMs

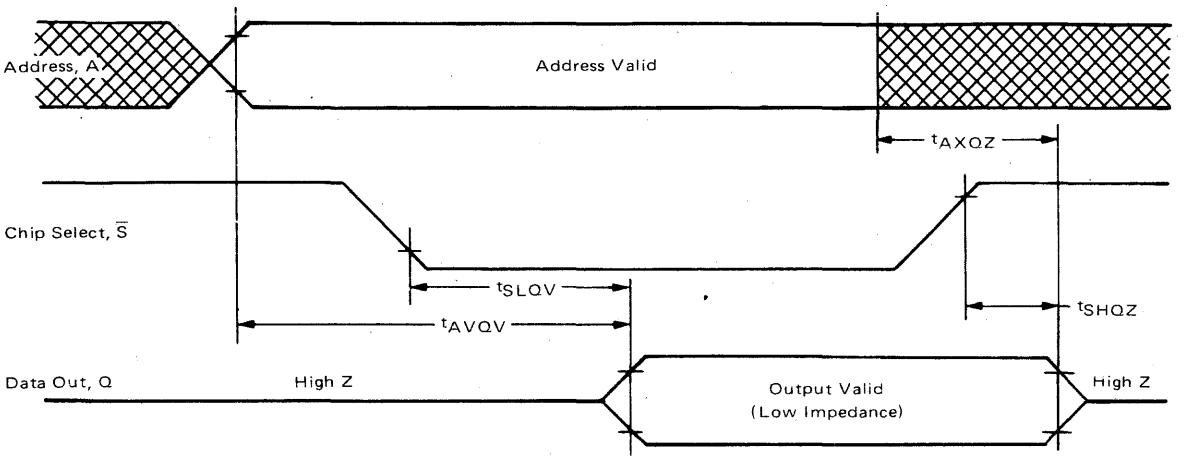
TIMING PARAMETER ABBREVIATIONS



The transition definitions used in this data sheet are:

H = transition to high
L = transition to low
V = transition to valid
X = transition to invalid or don't care
Z = transition to off (high impedance)

TIMING LIMITS

The table of timing values shows either a minimum or a maximum limit for each parameter. Input requirements are specified from the external system point of view. Thus, address setup time is shown as a minimum since the system must supply at least that much time (even though most devices do not require it). On the other hand, responses from the memory are specified from the device point of view. Thus, the access time is shown as a maximum since the device never provides data later than that time.

READ OPERATION TIMING DIAGRAM

DC PROGRAMMING CONDITIONS AND CHARACTERISTICS

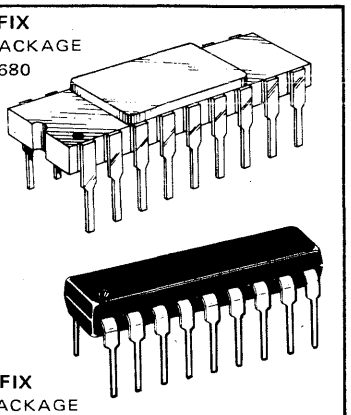
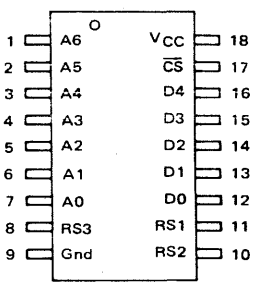
128c x 7 x 5
HORIZONTAL-SCAN
CHARACTER GENERATOR



128c X 7 X 5 CHARACTER GENERATOR

The MCM6670 is a mask-programmable horizontal-scan (row select) character generator containing 128 characters in a 5 X 7 matrix. A 7-bit address code is used to select one of the 128 available characters, and a 3-bit row select code chooses the appropriate row to appear at the outputs. The rows are sequentially displayed, providing a 7-word sequence of 5 parallel bits per word for each character selected by the address inputs.

The MCM6674 is a preprogrammed version of the MCM6670. The complete pattern of this device is contained in this data sheet.



- Fully Static Operation
- TTL Compatibility
- Single ±10% +5 Volt Power Supply
- 18-Pin Package
- Diagonal Corner Power Supply Pins
- Fast Access Time, 350 ns (max)

CUSTOM PROGRAMMING FOR MCM6670

By the programming of a single photomask, the customer may specify the content of the MCM6670/MCM66700 Encoding of the photomask is done with the aid of a computer to provide quick, efficient implementation of the custom bit pattern while reducing the cost of implementation.

Information for the custom memory content may be sent to Motorola in the following forms, in order of preference:

1. Hexadecimal coding using IBM Punch Cards
2. Hexadecimal coding using ASCII Paper Tape Punch

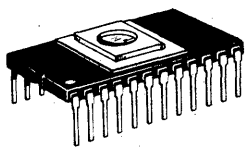
2048 X 8-BIT UV ERASABLE PROM

The MCM2716/27A16 is a 16,384-bit Erasable and Electrically Reprogrammable PROM designed for system debug usage and similar applications requiring nonvolatile memory that could be reprogrammed periodically. The transparent lid on the package allows the memory content to be erased with ultraviolet light.



For ease of use, the device operates from a single power supply and has a static power-down mode. Pin-for-pin mask programmable ROMS are available for large volume production runs of systems initially using the MCM2716/27A16.

- Single ±10% 5 V Power Supply
- Automatic Power-down Mode (Standby)
- Organized as 2048 Bytes of 8 Bits
- Low Power Dissipation
- TTL Compatible During Read and Program
- Maximum Access Time = 450 ns MCM2716
  350 ns MCM27A16
- Pin Equivalent to Intel's 2716
- Pin Compatible to MCM68A316E Mask Programmable ROMs

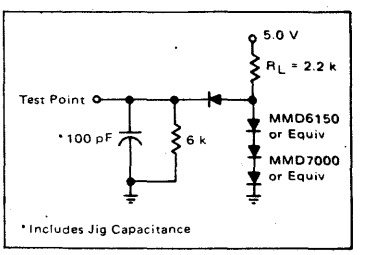
(Output Enable = V_{IL})

NOTE 2: t_{ELQV} is referenced to $\overline{E}$/Progr or stable address, whichever occurs last.

DC OPERATING CONDITIONS AND CHARACTERISTICS
(Full operating voltage and temperature range unless otherwise noted)

RECOMMENDED DC READ OPERATING CONDITIONS (T_A = 0° to +70°C)



Parameter		Symbol	Min	Nom	Max	Unit
Supply Voltage*	MCM2716	V_{CC}	4.75	5.0	5.25	Vdc
	MCM27A16		4.5	5.0	5.5	
		V_{PP}	V_{CC} – 0.6	5.0	V_{CC} + 0.6	
Input High Voltage		V_{IH}	2.0	–	V_{CC} + 1.0	Vdc
Input Low Voltage		V_{IL}	-0.1	–	0.8	Vdc

READ OPERATION DC CHARACTERISTICS

Characteristic	Condition	Symbol	Min	Typ	Max	Unit
Address, $\overline{G}$ and $\overline{E}$/Progr Input Sink Current	V_{in} = 5.25 V	I_{in}	–	–	10	μA
Output Leakage Current	V_{out} = 5.25 V, $\overline{G}$ = 5.0 V	I_{LO}	–	–	10	μA
V_{CC} Supply Current* (Standby)	$\overline{E}$/Progr = V_{IH}, $\overline{G}$ = V_{IL}	I_{CC1}	–	10	25	mA
V_{CC} Supply Current* (Active)	$\overline{G}$ = $\overline{E}$/Progr = V_{IL}	I_{CC2}	–	57	100	mA
V_{PP} Supply Current*	V_{PP} = 5.85 V	I_{PP1}	–	–	5.0	mA
Output Low Voltage	I_{OL} = 2.1 mA	V_{OL}	–	–	0.45	V
Output High Voltage	I_{OH} = -400 μA	V_{OH}	2.4	–	–	V

*V_{CC} must be applied simultaneously or prior to V_{PP}. V_{CC} must also be switched off simultaneously with or after V_{PP}. With V_{PP} connected directly to V_{CC} during the read operation, the supply current would be the sum of I_{PP1} and I_{CC}. The additional 0.6 V tolerance on V_{PP} makes it possible to use a driver circuit for switching the V_{PP} supply pin from V_{CC} in Read mode to +25 V for programming. Typical values are for T_A = 25°C and nominal supply voltages.

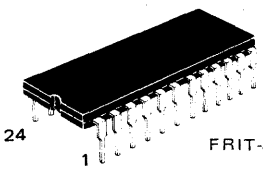
8192-BIT READ ONLY MEMORIES
ROW SELECT CHARACTER GENERATORS

The MCM66700 is a mask-programmable 8192-bit horizontal-scan (row select) character generator. It contains 128 characters in a 7 X 9 matrix, and has the capability of shifting certain characters that normally extend below the baseline such as j, y, g, p, and q. Circuitry is supplied internally to effectively lower the whole matrix for this type of character—a feature previously requiring external circuitry.

A seven-bit address code is used to select one of the 128 available characters. Each character is defined as a specific combination of logic 1s and 0s stored in a 7 X 9 matrix. When a specific four-bit binary row select code is applied, a word of seven parallel bits appears at the output. The rows can be sequentially selected, providing a nine-word sequence of seven parallel bits per word for each character selected by the address inputs. As the row select inputs are sequentially addressed, the devices will automatically place the 7 X 9 character in one of two preprogrammed positions on the 16-row matrix, with the positions defined by the four row select inputs. Rows that are not part of the character are automatically blanked.

The devices listed are preprogrammed versions of the MCM66700. They contain various sets of characters to meet the requirements of diverse applications. The complete patterns of these devices are contained in this data sheet.



- Fully Static Operation
- Fully TTL Compatible with Three-State Outputs
- CMOS and MPU Compatible, Single ±10% 5 Volt Supply
- Shifted Character Capability
  (Except MCM66720, MCM66730, and MCM66734)
- Maximum Access Time = 350 ns
- 4 Programmable Chip Selects (0, 1, or X)
- Pin-for-Pin Replacement for the MCM6570, Including All Standard Patterns

MEMORY OPERATION (Using Positive Logic)

Most positive level = 1, most negative level = 0.

Address

To select one of the 128 characters, apply the appropriate binary code to the Address inputs (A0 through A6).

Row Select

To select one of the rows of the addressed character to appear at the seven output lines, apply the appropriate binary code to the Row Select inputs (RS0 through RS3).

Shifted Characters

These devices have the capability of displaying characters that descend below the bottom line (such as lowercase letters j, y, g, p, and q). Internal circuitry effectively drops the whole matrix for this type of character. Any character can be programmed to occupy either of the two positions in a 7 X 16 matrix. (Shifted characters are not available on MCM66720, MCM66730, or MCM66734.)

Output

For these devices, an output dot is defined as a logic 1 level, and an output blank is defined as a logic 0 level.

Programmable Chip Select

The MCM66700 has four Chip Select inputs that can be programmed with a 1, 0, or don't care (not connected). A don't care must always be the highest chip select pin or pins. All standard patterns have Don't Care Chip Select—except MCM66751.

DISPLAY FORMAT

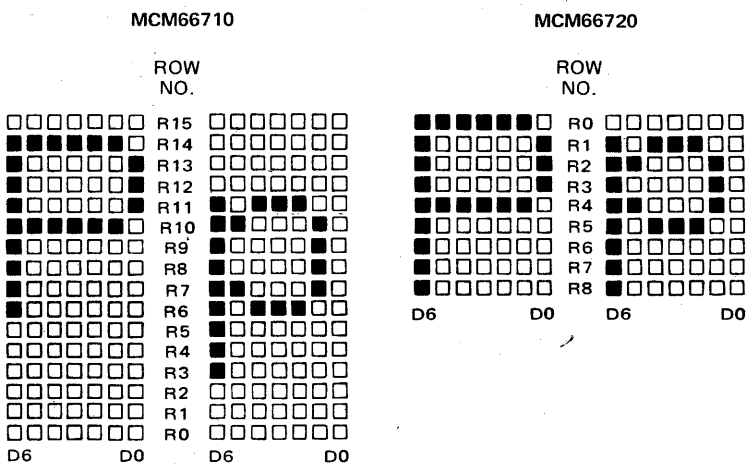

Figure 1 shows the relationship between the logic levels at the row select inputs and the character row at the outputs. The MCM66700 allows the user to locate the basic 7 X 9 font anywhere in the 7 X 16 array. In addition, a shifted font can be placed anywhere in the same 7 X 16 array. For example, the basic MCM66710 font is established in rows R14 through R6. All other rows are automatically blanked. The shifted font is established in rows R11 through R3, with all other rows blanked. Thus, while any one character is contained in a 7 X 9 array, the MCM66710 requires a 7 X 12 array on the CRT screen to contain both normal and descending characters. Other uses of the shift option may require as much as the full 7 X 16 array, or as little as the basic 7 X 9 array (when no shifting occurs, as in the MCM66720).

The MCM66700 can be programmed to be scanned either from bottom to top or from top to bottom. This is achieved through the option of assigning row numbers in ascending or descending count, as long as both the basic font and the shifted font are the same. For example, an up counter will scan the MCM66710 from bottom to top, whereas an up counter will scan the MCM66714 from top to bottom (see Figures 7 and 8 for row designation).

FIGURE 1 – ROW SELECT INPUT CODE AND SAMPLE CHARACTERS FOR MCM66710 AND MCM66720

CUSTOM PROGRAMMING FOR MCM66700

By the programming of a single photomask, the customer may specify the content of the MCM66700. Encoding of the photomask is done with the aid of a computer to provide quick, efficient implementation of the custom bit pattern while reducing the cost of implementation.

Information for the custom memory content may be sent to Motorola in the forms specified on the Motorola data sheet.

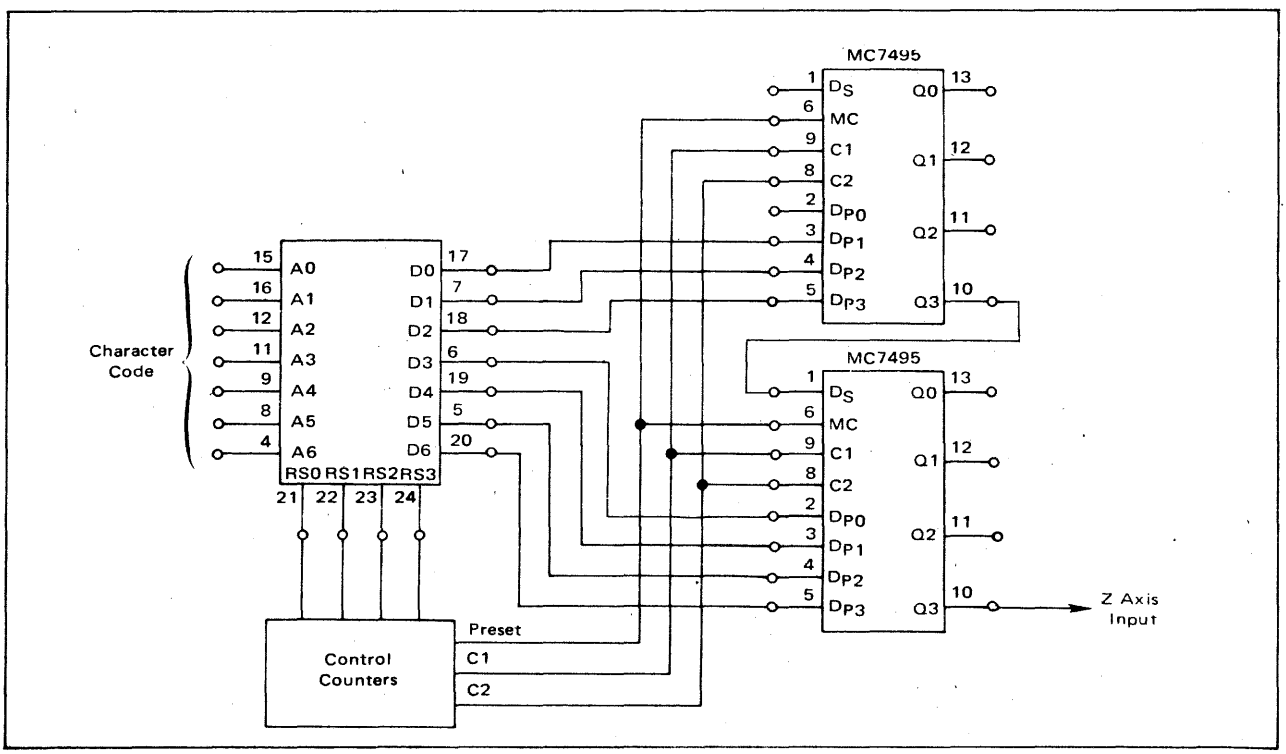
MCM66700 Series Pin Assignment

MCM6570 Series Pin Assignment



APPLICATIONS INFORMATION

One important application for the MCM66700 series is in CRT display systems (Figure 18). A set of buffer shift registers or random access memories applies a 7-bit character code to the input of the character generator, which then supplies one row of the character according to the count at the four row select inputs. As each row is available, it is put into the TTL MC7495 shift registers. The parallel information in these shift registers is clocked serially out to the Z-axis where it modulates the raster to form the character.

The MCM66700 series require one power supply of +5.0 volts. When powering this device from laboratory or system power supplies, it is important that the Absolute Maximum Ratings not be exceeded or device failure can result. Some power supplies exhibit spikes or glitches on their outputs when the ac power is switched on and off.

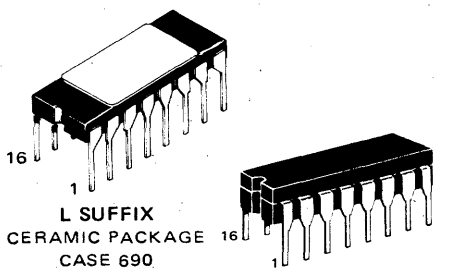
MCM4116

16,384-BIT DYNAMIC RANDOM ACCESS MEMORY

MOS

(N-CHANNEL)

16,384-BIT DYNAMIC RANDOM ACCESS MEMORY

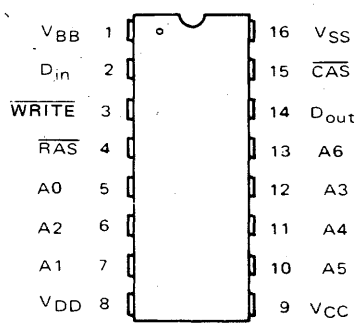


The MCM4116 is a 16,384-bit, high-speed dynamic Random Access Memory designed for high-performance, low-cost applications in mainframe and buffer memories and peripheral storage. Organized as 16,384 one-bit words and fabricated using Motorola's highly reliable N-channel double-polysilicon technology, this device optimizes speed, power, and density tradeoffs.

By multiplexing row and column address inputs, the MCM4116 requires only seven address lines and permits packaging in Motorola's standard 16-pin dual in-line packages. This packaging technique allows high system density and is compatible with widely available automated test and insertion equipment. Complete address decoding is done on chip with address latches incorporated.

All inputs are TTL compatible, and the output is 3-state TTL compatible. The data output of the MCM4116 is controlled by the column address strobe and remains valid from access time until the column address strobe returns to the high state. This output scheme allows higher degrees of system design flexibility such as common input/output operation and two dimensional memory selection by decoding both row address and column address strobes.

The MCM4116 incorporates a one-transistor cell design and dynamic storage techniques, with each of the 128 row addresses requiring a refresh cycle every 2 milliseconds.



- Flexible Timing with Read-Modify-Write, RAS-Only Refresh, and Page-Mode Capability
- Industry Standard 16-Pin Package
- 16,384 X 1 Organization
- ±10% Tolerance on All Power Supplies
- All Inputs are Fully TTL Compatible
- Three-State Fully TTL-Compatible Output
- Common I/O Capability When Using "Early Write" Mode
- On-Chip Latches for Addresses and Data In
- Low Power Dissipation – 462 mW Active, 20 mW Standby (Max)
- Fast Access Time Options: 150 ns – MCM4116L-15, C-15
  200 ns – MCM4116L-20, C-20
  250 ns – MCM4116L-25, C-25
  300 ns – MCM4116L-30, C-30
- Easy Upgrade from 16-Pin 4K RAMs
- Pin Compatible with 2117, 2116, 6616, μPD416, and 4116

PIN ASSIGNMENT

PIN NAMES

A0–A6	Address Inputs
$\overline{CAS}$	Column Address Strobe
D_{in}	Data In
D_{out}	Data Out
$\overline{RAS}$	Row Address Strobe
$\overline{WRITE}$	Read/Write Input
V_{BB}	Power (-5 V)
V_{CC}	Power (+5 V)
V_{DD}	Power (+12 V)
V_{SS}	Ground

ABSOLUTE MAXIMUM RATINGS (See Note 1)

Rating	Symbol	Value	Unit
Voltage on Any Pin Relative to V_{BB}	V_{in},V_{out}	-0.5 to +20	Vdc
Operating Temperature Range	T_A	0 to +70	°C
Storage Temperature Range	T_{stg}	–65 to +150	°C
Power Dissipation	P_D	1.0	W
Data Out Current	I_{out}	50	mA

NOTE 1: Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded. Functional operation should be restricted to RECOMMENDED OPERATING CONDITIONS. Exposure to higher than recommended voltages for extended periods of time could affect device reliability.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit.

This is advance information and specifications are subject to change without notice.

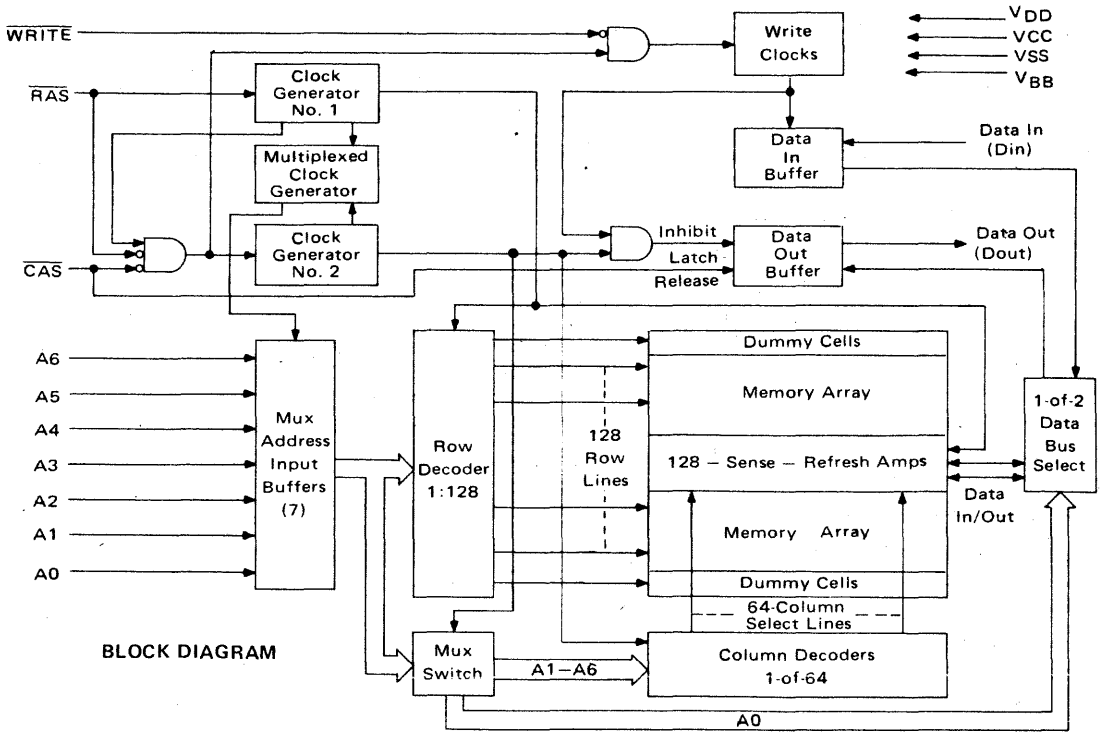
DC OPERATING CONDITIONS AND CHARACTERISTICS

(Full operating voltage and temperature range unless otherwise noted.)

RECOMMENDED OPERATING CONDITIONS



Parameter	Symbol	Min	Typ	Max	Unit	Notes
Supply Voltage	V_{DD}	10.8	12.0	13.2	Vdc	1
	V_{CC}	4.5	5.0	5.5	Vdc	1, 2
	V_{SS}	0	0	0	Vdc	1
	V_{BB}	-4.5	-5.0	-5.5	Vdc	1
Logic 1 Voltage, $\overline{RAS}$, $\overline{CAS}$, $\overline{WRITE}$	V_{IHC}	2.7	–	7.0	Vdc	1
Logic 1 Voltage, all inputs except $\overline{RAS}$, $\overline{CAS}$, $\overline{WRITE}$	V_{IH}	2.4	–	7.0	Vdc	1
Logic 0 Voltage, all inputs	V_{IL}	-1.0	–	0.8	Vdc	1

DC CHARACTERISTICS (V_{DD} = 12 V ± 10%, V_{CC} = 5.0 V ± 10%, V_{BB} = -5.0 V ± 10%, V_{SS} = 0 V, T_A = 0 to 70°C.)

Characteristic	Symbol	Min	Max	Units	Notes
Average V_{DD} Power Supply Current	I_{DD1}	–	35	mA	4
V_{CC} Power Supply Current	I_{CC}	–	–	mA	5
Average V_{BB} Power Supply Current	$I_{BB1,3}$	–	200	μA	
Standby V_{BB} Power Supply Current	I_{BB2}	–	100	μA	
Standby V_{DD} Power Supply Current	I_{DD2}	–	1.5	mA	6
Average V_{DD} Power Supply Current during "$\overline{RAS}$ only" cycles	I_{DD3}	–	27	mA	4
Input Leakage Current (any input)	$I_{I(L)}$	–	10	μA	
Output Leakage Current	$I_{O(L)}$	–	10	μA	6, 7
Output Logic 1 Voltage @ I_{out} = -5 mA	V_{OH}	2.4	–	Vdc	2
Output Logic 0 Voltage @ I_{out} = 4.2 mA	V_{OL}	–	0.4	Vdc	

NOTES:

1. All voltages referenced to V_{SS}. V_{BB} must be applied before and removed after other supply voltages.
2. Output voltage will swing from V_{SS} to V_{CC} under open circuit conditions. For purposes of maintaining data in power-down mode, V_{CC} may be reduced to V_{SS} without affecting refresh operations. V_{OH}(min) specification is not guaranteed in this mode.
3. Several cycles are required after power-up before proper device operation is achieved. Any 8 cycles which perform refresh are adequate.
4. Current is proportional to cycle rate; maximum current is measured at the fastest cycle rate.
5. I_{CC} depends upon output loading. The V_{CC} supply is connected to the output buffer only.
6. Output is disabled (open-circuit) and $\overline{RAS}$ and $\overline{CAS}$ are both at a logic 1.
7. $0 V \leq V_{out} \leq +5.5 V$.
8. Capacitance measured with a Boonton Meter or effective capacitance calculated from the equation: $C = \frac{I\Delta_t}{\Delta V}$

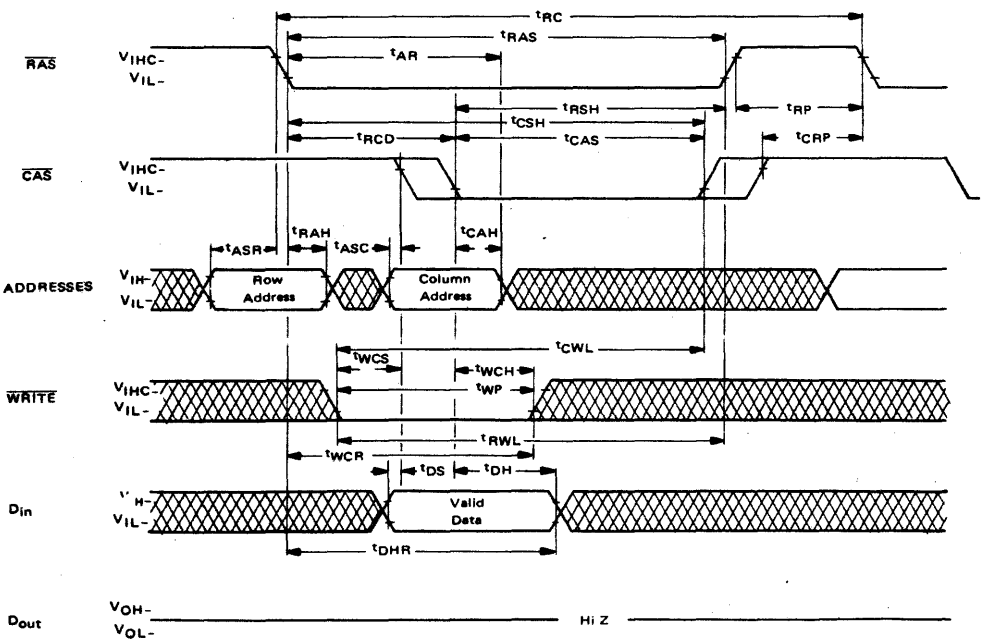
Output Capacitance (D_{out})	C_o	5.0	7.0	pF	7, 9

NOTES: (continued)



9. AC measurements assume t_T = 5.0 ns.
10. Assumes that $t_{RCD} + t_T \leq t_{RCD}$ (max).
11. Assumes that $t_{RCD} + t_T \geq t_{RCD}$ (max).
12. Measured with a load circuit equivalent to 2 TTL loads and 100 pF.
13. Operation within the t_{RCD} (max) limit ensures that t_{RAC} (max) can be met. t_{RCD} (max) is specified as a reference point only; if t_{RCD} is greater than the specified t_{RCD} (max) limit, then access time is controlled exclusively by t_{CAC}.
14. V_{IHC} (min) or V_{IH} (min) and V_{IL} (max) are reference levels for measuring timing of input signals. Also, transistion times are measured between V_{IHC} or V_{IH} and V_{IL}.
15. These parameters are referenced to $\overline{CAS}$ leading edge in random write cycles and to $\overline{WRITE}$ leading edge in delayed write or read-modify-write cycles.
16. t_{WCS}, t_{CWD} and t_{RWD} are not restrictive operating parameters. They are included in the data sheet as electrical characteristics only: If $t_{WCS} \geq t_{WCS}$ (min), the cycle is an early write cycle and the data out pin will remain open circuit (high impedance) throughout the entire cycle; If $t_{CWD} \geq t_{CWD}$ (min) and $t_{RWD} \geq t_{RWD}$ (min), the cycle is a read-write cycle and the data out will contain data read from the selected cell; If neither of the above sets of conditions is satisfied the condition of the data out (at access time) is indeterminate.

MCM2147

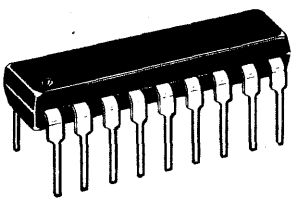
Advance Information

MOS

(N-CHANNEL, SILICON-GATE)

4096-BIT STATIC RANDOM ACCESS MEMORY

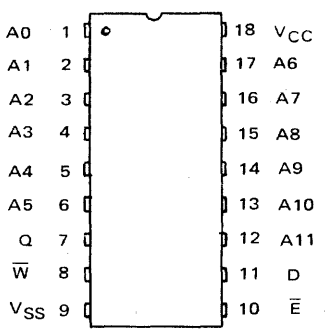
4096-BIT STATIC RANDOM ACCESS MEMORY



The MCM2147 is a 4096-bit static random access memory organized as 4096 words by 1-bit using Motorola's N-channel silicon-gate MOS technology. It uses a design approach which provides the simple timing features associated with fully static memories and the reduced standby power associated with semi-static and dynamic memories. This means low standby power without the need for clocks, nor reduced data rates due to cycle times that exceed access times.

$\overline{E}$ controls the power-down feature. It is not a clock but rather a chip select that affects power consumption. In less than a cycle time after $\overline{E}$ goes high, deselect mode, the part automatically reduces its power requirements and remains in this low-power standby mode as long as $\overline{E}$ remains high. This feature results in system power savings as great as 85% in larger systems, where most devices are deselected. The automatic power-down feature causes no performance degradation.

The MCM2147 is in an 18 pin dual in-line package with the industry standard pinout. It is TTL compatible in all respects. The data out has the same polarity as the input data. A data input and a separate three-state output provide flexibility and allow easy OR-ties.



- Fully Static Memory — No Clock or Timing Strobe Required
- Single ±10% +5 V Supply
- High Density 18 Pin Package
- Automatic Power-Down
- Directly TTL Compatible—All Inputs and Outputs
- Separate Data Input and Output
- Three-State Output

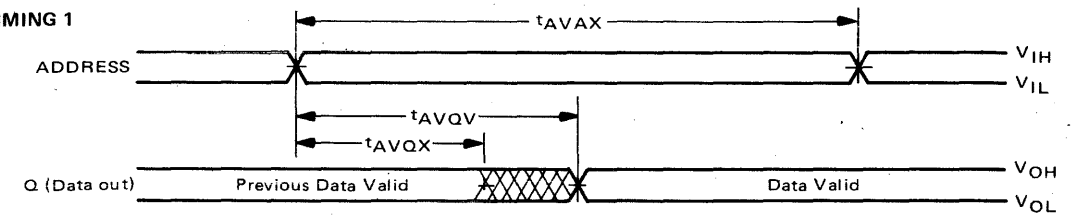
TIMING PARAMETER ABBREVIATIONS

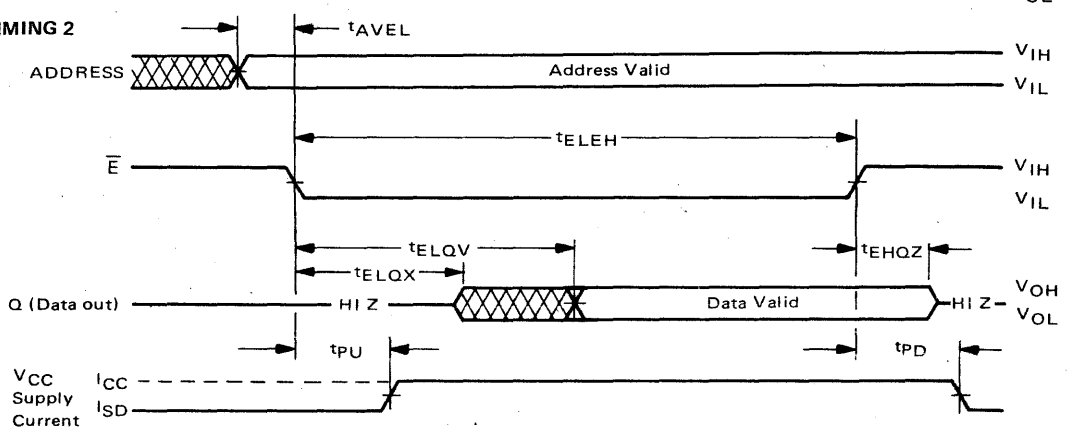
t X X X X

- signal name from which interval is defined
- transition direction for first signal
- signal name to which interval is defined
- transition direction for second signal



The transition definitions used in this data sheet are:

- H = transition to high
- L = transition to low
- V = transition to valid
- X = transition to invalid or don't care
- Z = transition to off (high impedance)



TIMING LIMITS

The table of timing values shows either a minimum or a maximum limit for each parameter. Input requirements are specified from the external system point of view. Thus, address setup time is shown as a minimum since the system must supply at least that much time (even though most devices do not require it). On the other hand, responses from the memory are specified from the device point of view. Thus, the access time is shown as a maximum since the device never provides data later than that time.

DEVICE DESCRIPTION

The MCM2147 is produced with a high-performance MOS technology which combines on-chip substrate bias generation with device scaling to achieve high speed. The speed-power product of this process is about four times better than earlier MOS processes.

This gives the MCM2147 its high speed, low power and ease-of-use. The low-power standby feature is controlled with the $\overline{E}$ input. *$\overline{E}$ is not a clock and does not have to be cycled.* This allows the user to tie $\overline{E}$ directly to system addresses and use the line as part of the normal decoding logic. Whenever the MCM2147 is deselected, it automatically reduces its power requirements.

SYSTEM POWER SAVINGS

The automatic power-down feature adds up to significant system power savings. Unselected devices draw low standby power and only the active devices draw active power. Thus the average power consumed by a device declines as the system size increases, asymptotically approaching the standby power level as shown in Figure 2.

The automatic power-down feature is obtained without any performance degradation, since access time from chip enable is ⩽ access time from address valid. Also the fully static design gives access time equal cycle time so multiple read or write operations are possible during a single select period. The resultant data rates are 14.3 MHz and 18 MHz for the MCM2147-70 and MCM2147-55 respectively.

DECOUPLING AND BOARD LAYOUT CONSIDERATIONS

The power switching characteristic of the MCM2147 requires careful decoupling. It is recommended that a 0.1 μF to 0.3 μF ceramic capacitor be used on every other device, with a 22 μF to 47 μF bulk electrolytic decoupler every 16 devices. The actual values to be used will depend on board layout, trace widths and duty cycle.

Power supply gridding is recommended for PC board layout. A very satisfactory grid can be developed on a two-layer board with vertical traces on one side and horizontal traces on the other, as shown in Figure 3. If fast drivers are used, terminations are recommended on input signal lines to the MCM2147 because significant reflections are possible when driving their high impedance inputs. Terminations may be required to match the impedance of the line to the driver.

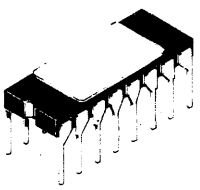
Advance Information

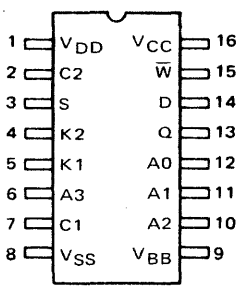
MOS
(N-CHANNEL, SILICON-GATE)



65,536 X 1-BIT DYNAMIC SERIAL MEMORY

65,536 X 1-BIT DYNAMIC SERIAL MEMORY

The MCM0464 device is a 65,536-bit dynamic serial memory configured as 16 randomly accessible shift registers, each 4096 bits long. Each of these shift registers is designed utilizing Charge Coupled Device (CCD) techniques along with the interleaved Serial-Parallel-Serial (SPS) register structure which features both low power and high density characteristics. The high density of the MCM0464 is further enhanced through the use of an electrode-per-bit memory cell approach. The high density permits packaging the memory in a standard 16-pin dual in-line package which allows the construction of highly dense memory systems using widely available automated testing and insertion equipment.



Furthermore, this buried-channel CCD memory is fabricated using our double-poly N-channel silicon-gate process. This process allows the MCM0464 to be a high performance, state-of-the-art memory circuit which is manufacturable in volume quantities.

- Industry Standard 16 Pin Dual In-Line Package
- Operating Frequency Range: 1 MHz to 5 MHz
- Low Capacitance TTL-Compatible Inputs (Except Clocks)
- 3-State, TTL-Compatible, Latched Data Output
- Output Drive Capability: 3.5 mA into 100 pF Load
- Low Capacitance 12 V Clocks:
  C1 and C2: 100 pF (typ)
  K1 and K2: 30 pF (typ)
- Low Power
  Normal Operation: < 400 mW (max) @ f_{max}
  Standby: < 70 mW (max) @ f_{min}
- Standard Power Supplies (+12 V, +5 V, and −5 V)

FUNCTIONAL DESCRIPTION

Organization – The MCM0464 is a 65,536 X 1 bit dynamic serial memory organized internally as 16 dynamic shift registers (or blocks) of 4096 bits each in length. These 16 shift register blocks are randomly accessible through four internally decoded Address inputs (A0-A3). When a given register is selected, its input and output are internally connected (as needed) to the D and Q pins, respectively, thus permitting simultaneous read and write operations.

Architecture – Each of the sixteen shift register blocks is implemented using a Serial-Parallel-Serial (SPS) register architecture. In this approach N data bits are sequentially shifted into a "serial" input register. When full, the entire N-bit word is shifted in parallel into N "parallel" registers of M bits in length, as illustrated in Figure 1. At the other end of this parallel register structure, bits are loaded in parallel into an N-bit serial output register. Bits in this register are then shifted out toward the output latch and then are automatically recirculated back to the input serial register unless a Write operation is specified.

The primary advantages of this type of architecture include very high density, low power, and low clock capacitance. These features all result from the fact that in the SPS architecture the parallel registers which encompass most of the total storage capacity within each block are shifted at a considerably slower rate (f_{in}/N) than clock rate of the input or output serial registers, f_{in}.

In actuality, each 4096-bit block of the MCM0464 is implemented using an "interleaved" SPS structure in which each bit of the serial input register services two parallel registers rather than just one. The same is true for the output serial register. In addition, "electrode-per-bit" design techniques are used to reduce the effective cell size by minimizing the number of electrodes used to store each bit of information. These techniques obviously enhance the memory density considerably. The dimensions of the MCM0464 interleaved SPS structure are 32-bit input and output serial registers and 64 parallel registers, each 63 bits in length. See Figure 2. These dimensions were chosen in order to optimize the power/density/latency tradeofffs inherent in the CCD memory approach.

Clocks – The MCM0464 requires four MOS level clocks: Two high frequency (1 to 5 MHz) serial clocks and two low frequency transfer clocks. The serial clocks, C1 and C2, control the movement of data within the input and output serial registers of each 4096-bit block and have a frequency equal to the data rate. The transfer clock K1 is used to transfer data from the input serial register to the parallel registers while the transfer clock K2 is used to transfer data from the parallel registers to the output serial register of each block. The data present in the parallel registers is shifted by internally generated ripple clocks. This ripple clock technique allows a high bit-packing density approaching one electrode per bit.

To achieve proper transfer phasing, the two transfer clocks are asymmetrical about a 32-cycle interval (31.5 and 32.5 cycles) but symmetrical about a 64-cycle interval. The phasing between these transfer clocks alternates in order to achieve correct bit storage in each block. When K1 occurs during C1 time, K2 occurs during C2 time 1.5 cycles prior to K1. When K1 occurs during C2 time, K2 occurs during C1 time 2.5 cycles prior to K1. Figure 3 illustrates the clock phase relationships.

FIGURE 3 – MCM0464 CLOCKS

CONTROLS

In addition to the four Address inputs (A0 through A3), other TTL level control signals available on the MCM0464 include Write Enable ($\overline{W}$) and Chip Select (S). The S input, along with the address information, is presented during C1 high time and dynamically latched with the trailing edge of C1 while simultaneously disabling both the address and S buffers. This action prevents changes that occur on the external pins from entering the internal circuitry when C1 is low. The $\overline{W}$ control signal determines whether new data from the D input pin, or recirculated output data, is presented to the input of the addressed block.

MODES OF OPERATION

Standby (Recirculate-only cycle) – In Standby mode (S low), the contents of all 16 blocks are recirculated automatically, and the device disregards the $\overline{W}$, Address, and D inputs. The output latch goes into the high impedance state after the trailing edge of the C1 clock. Minimum device power results when operating the device in the recirculate mode with minimum C1 and C2 pulse widths at the lowest allowed frequency.

Read-Recirculate Mode – In this mode of operation ($\overline{W}$ high and S high) the data from the selected block is presented to the output buffer immediately following the leading edge of C2 and appears at the output, Q, after a delay equal to the access time t_{Acc}. Thus, the access time is referenced from the leading edge of the C2 pulse and is independent of the duration of C2. The output data is latched and remains valid at the Q output pin until the end of the C1 clock pulse in the next cycle. The data present in all 16 blocks automatically recirculates from the output back to the input regardless of the address inputs, provided that $\overline{W}$ remains inactive throughout the cycle.

Read and Write Mode – In the Read and Write mode ($\overline{W}$ low and S high), the output data from the selected block is available at the output pin as in the read-recirculate mode; however, the recirculate path of that particular block is disabled. Input data present at the D input pin during C2 is written into the selected block by the falling edge of C2, while the other 15 blocks automatically recirculate their contents. This form of an "early-write" cycle ($\overline{W}$ low prior to the falling edge of C1) requires that both $\overline{W}$ and D have set-up times with respect to the trailing edge of C1. In fact, for successive write operations handled in this mode, $\overline{W}$ may be held low continuously without returning it to the high state between cycles. A "delayed-write" cycle ($\overline{W}$ goes low after the trailing edge of the C1 clock pulse) is also possible and is discussed in the next paragraph as a subset of the RMW operating mode.

Read-Modify-Write Mode – The Read-Modify-Write Mode (S high, $\overline{W}$ high goes low) is simplified by the fact that the MCM0464 is always in the read mode whenever it is selected (S high). Since the access time is referenced to the leading edge of C2 and the setup times of $\overline{W}$ and D are referenced to the trailing edge of C2, this mode of operation requires an extended C2 high time in order to provide the required modify time. This "stretched" C2 high time may be determined by the following relationship:

$$t_{C2HC2L} = t_{CHQV} + t_{Modify} + t_{DVCL} + t_{WLCL} + t_T$$

©IC MASTER 1979

The modify time, t_{Modify}, is determined by the memory designer and is dependent on the delays of the external logic used to modify the output data. The Read-Modify-Write (RMW) cycle time then, is given by:

$$\text{Cycle Time} = t_{C1HC1L} + t_{C1LC2H} + t_{C2HC2L} + t_{C2LC1H} + 4t_T$$

where tC2HC2L is the new "stretched" version of the C2 clock pulse.

If no modification of output data is required, then this operating mode reduces to a "delayed-write" mode in which D and W may occur after the C1 clock pulse.

MEMORY START-UP

When the MCM0464 is initially powered up, the V_{BB} supply (i.e., the -5 volt supply) should be applied to the memory before the other supplies. This action results in greater protection against accidental violation of the voltage limits specified in the Absolute Maximum Ratings section and, in general, enhances the long term reliability of the memory.

In order to clear the memory of extraneous charge following power-up, the MCM0464 must be clocked through a minimum of 32,000 cycles of any type before a valid memory cycle should be attempted.

ABSOLUTE MAXIMUM RATINGS (See Note)

Rating	Symbol	Value	Unit
Voltage on Any Pin Relative to V_{BB} ($V_{SS} - V_{BB} \geq 4.5$ V)	V_{in}, V_{out}	-0.5 to +20	Vdc
Operating Temperature Range	T_A	0 to +70	°C
Storage Temperature Range	T_{stg}	-55 to +150	°C
Power Dissipation	P_D	1.0	W

NOTE: Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded. Functional operation should be restricted to RECOMMENDED OPERATING CONDITIONS. Exposure to higher than recommended voltage for extended periods of time could affect device reliability.

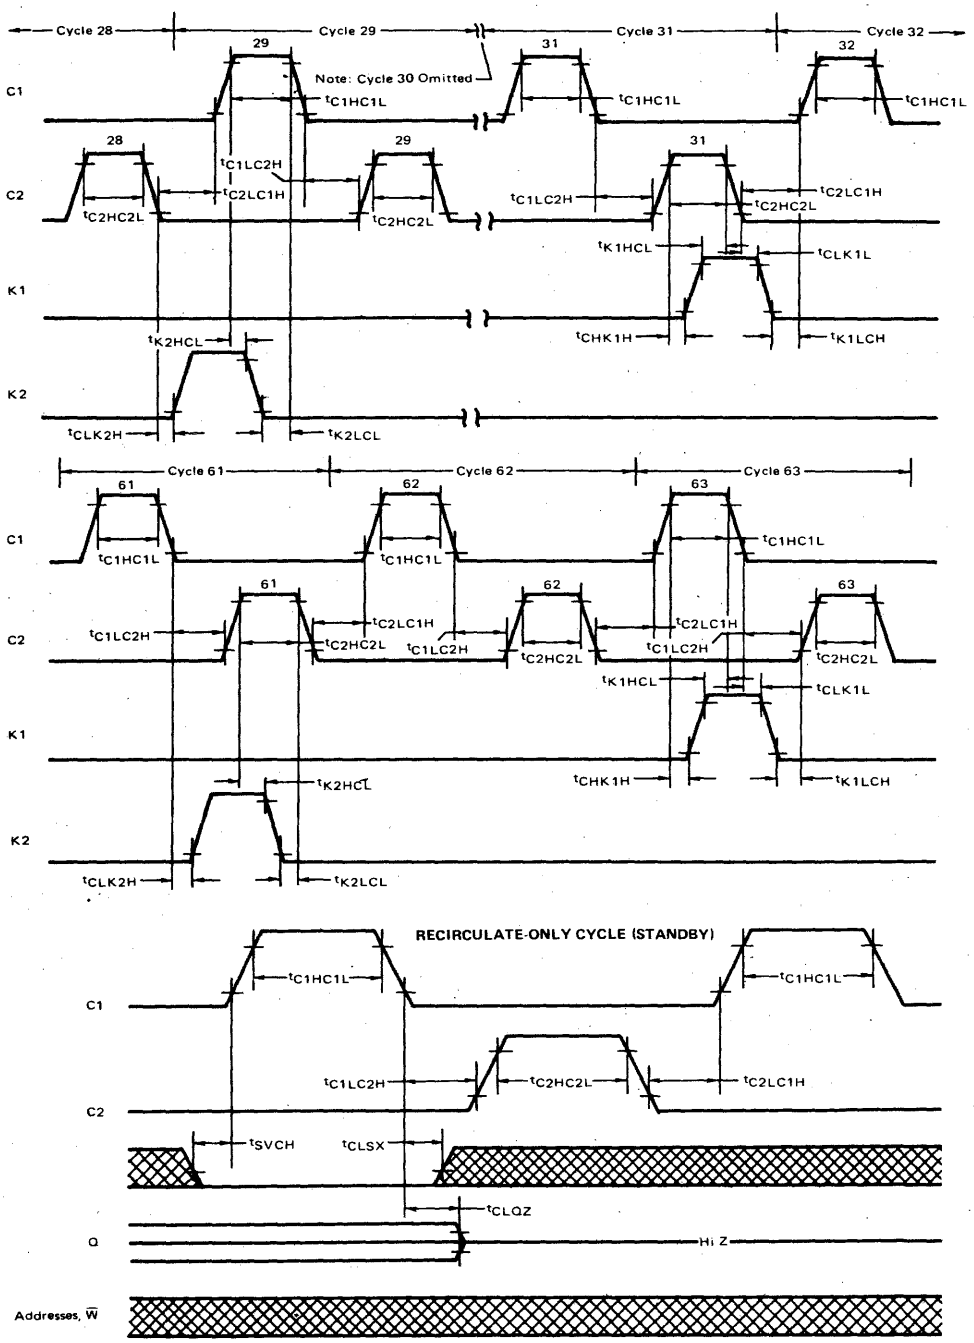
NOTES:

1. All voltages are measured with respect to V_{SS}.
2. The differential voltage between a low for any clock input and a low for any other clock input should not exceed 0.8 V.
3. Current levels at both minimum and maximum frequencies are specified for minimum C1 and C2 clock pulse widths. See Figure 4.
4. Measured at maximum frequency and V_{BB} = -5.5 V.
5. Measured with I_{out} = -2.5 mA.
6. Measured with I_{out} = 3.5 mA.
7. Input leakage current is measured with $V_{in} = V_{DD}$ for clock inputs and $V_{in} = V_{CC}$ for all other inputs.
8. Leakage current at the Q output pin is measured for both V_{out} equal to V_{CC} and V_{SS} when the output buffer is in the high impedance state.
9. Effective capacitance is calculated from the equation



$$C = I\frac{\Delta t}{\Delta V}$$

with ΔV = 12 V for clock inputs and with ΔV = 3 V for TTL pins while the device is active.

10. Maximum clock pulse widths are specified in order to limit power dissipation. See Figure 4 showing the relationship between power and clock pulse width.
11. Reference levels used for timing measurements are V_{IHC} (min) and V_{ILC} (max) for clock inputs and V_{IH} (min) and V_{IL} (max) for all other inputs. Transition times for both rise and fall are measured between these reference points.
12. Minimum and maximum frequency values assume clock transition times of 10 ns.
13. The Read-Recirculate command is performed by keeping $\overline{W}$ in the inactive state (i.e., high) for the prescribed set-up and hold times.
14. t_{DVCL} references D to the trailing edge of C1 in a Read-(early) Write cycle. However, in a Read-Modify-Write (i.e., delayed write) cycle, t_{DVCL} references D to the negative-going edge of $\overline{W}$.
15. t_{CLQZ} (max) defines the time at which the output achieves the open circuit condition and is not referenced to output voltage levels.
16. Measured with a load equivalent to two TTL loads and 100 pF.

CLOCK GENERATION CIRCUIT

The circuit shown below may be used to generate the four clocks required for operation of the MCM0464 with proper phase relationships from a single master clock. This master input frequency f_{in}, must be twice the desired data rate at the MCM0464 output pin. Since the input clock frequency is "squared-up" with a divide-by-two flipflop, the duty cycle of this clock is non-critical. A pulse edge at the input of the buffered delay line produces a sequence of delayed pulse edges from the A, B, C and D output taps. These delayed pulse edges are ANDed together to produce the required C1 and C2 clocks as well as the K1 and K2 transfer clocks. Since the transfer clocks are generated (but not necessarily used) every cycle, the outputs of the 6-bit, module 64 counter are decoded to enable selected transfer clock gates at counts of 29, 31, 61, and 63. Thus, K1 is passed along to the clock drivers only during cycles 31 and 63, while K2 is passed through only during cycles 29 and 61. These four counts are easily decoded with only 2 bits of the 6-bit, module 64 counter. These 6 bits are the lower order bits of the 12-bit, module 4096 loop counter required to define address locations within each 4K block and which will, in most cases be already present in the system.

SERIAL AND TRANSFER CLOCK GENERATION CIRCUIT

NOTE: All clock pulses are strictly a function of the edges of the input clock, i.e., pulse widths are *not* a function of frequency.

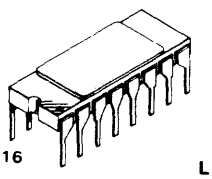
MCM4027

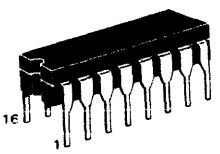
4096-BIT DYNAMIC RANDOM ACCESS MEMORY

The MCM4027 is a 4096-bit high-speed dynamic Random Access Memory designed for high-performance, low-cost applications in mainframe and buffer memories and peripheral storage. Organized as 4096 one-bit words and fabricated using Motorola's highly reliable N-channel silicon gate technology, this device optimizes speed, power, and density tradeoffs.



By multiplexing row and column address inputs, the MCM4027 requires only six address lines and permits packaging in Motorola's standard 16-pin dual in-line packages. Complete address decoding is done on chip with address latches incorporated.

All inputs are TTL compatible, and the output is 3-state TTL compatible. The MCM4027 incorporates a one-transistor cell design and dynamic storage techniques, with each of the 64 row addresses requiring a refresh cycle every 2.0 milliseconds.



- Maximum Access Time = 150 ns – MCM4027L2, C2
  200 ns – MCM4027L3, C3
  250 ns – MCM4027L4, C4
- Maximum Read and Write Cycle Time =
  320 ns – MCM4027L2, C2
  375 ns – MCM4027L3, C3, L4, C4
- Low Power Dissipation –
  470 mW Max (Active) 27 mW Max (Standby)
- 3-State Output for OR-Ties
- On-Chip Latches for Address, Chip Select, and Data In
- Power Supply Pins on Package Corners for Optimum Layout
- Industry Standard 16-Pin Package
- Page-Mode Capability
- Compatible with the Popular 2104/MK4096/MCM6604
- Second Source for MK4027
- Also Available: MCM4027L4BECS – Mil-883 Level B Processing
  MCM4027L4CECS – Mil-883 Level C Processing

OPERATING CHARACTERISTICS

ADDRESSING

The MCM4027 has six address inputs (A0–A5) and two clock signals designated Row Address Strobe ($\overline{RAS}$) and Column Address Strobe ($\overline{CAS}$). At the beginning of a memory cycle, the six low order address bits A0 through A5 are strobed into the chip with $\overline{RAS}$ to select one of the 64 rows. The row address strobe also initiates the timing that will enable the 64 column sense amplifiers. After a specified hold time, the row address is removed and the six high order address bits (A6–A11) are placed on the address pins. This address is then strobed into the chip with $\overline{CAS}$. Two of the 64 column sense amplifiers are selected by A1 through A5. A one of two data bus select is accomplished by A0 to complete the data selection. The Chip Select ($\overline{CS}$) is latched into the port along with the column addresses.

DATA OUTPUT

In order to simplify the memory system designed and reduce the total package count, the MCM4027 contains an input data latch and a buffered output data latch. The state of the output latch and buffer at the end of a memory cycle will depend on the type of memory cycle performed and whether the chip is selected or unselected for that memory cycle.

A chip will be unselected during a memory cycle if:

(1) The chip receives both $\overline{RAS}$ and $\overline{CAS}$ signals, but no $\overline{Chip\ Select}$ signal.

(2) The chip receives a $\overline{CAS}$ signal but no $\overline{RAS}$ signal. With this condition, the chip will be unselected regardless of the state of $\overline{Chip\ Select}$ input.

If, during a read, write, or read-modify-write cycle, the chip is unselected, the output buffer will be in the high impedance state at the end of the memory cycle. The output buffer will remain in the high impedance state until the chip is selected for a memory cycle.

For a chip to be selected during a memory cycle, it must receive the following signals: $\overline{RAS}$, $\overline{CAS}$, and $\overline{Chip\ Select}$. The state of the output latch and buffer of a selected chip during the following type of memory cycles would be:

(1) Read Cycle – On the negative edge of $\overline{CAS}$, the output buffer will unconditionally go to a high impedance state. It will remain in this state until access time. At this time, the output latch and buffer will assume the logic state of the data read from the selected cell. This output state will be maintained until the chip receives the next $\overline{CAS}$ signal.

(2) Write Cycle – If the $\overline{WE}$ input is switched to a logic 0 before the $\overline{CAS}$ transition, the output latch and buffer will be switched to the state of the data input at the end of the access time. This logic state will be maintained until the chip receives the next $\overline{CAS}$ signal.

(3) Read-Modify-Write – Same as read cycle.

DATA INPUT

Data to be written into a selected storage cell of the memory chip is first stored in the on-chip data latch. The gating of this latch is performed with a combination of the $\overline{WE}$ and $\overline{CAS}$ signals. The last of these signals to make a negative transition will strobe the data into the latch. If the $\overline{WE}$ input is switching to a logic 0 in the beginning of a write cycle, the falling edge of $\overline{CAS}$ strobes the data into the latch. The data setup and hold times are then referenced to the negative edge of $\overline{CAS}$.

If a read-modify-write cycle is being performed, the $\overline{WE}$ input would not make its negative transistion until after the $\overline{CAS}$ signal was enabled. Thus, the data would not be strobed into the latch until the negative transistion of $\overline{WE}$. The data setup and hold times would now be referenced to the negative edge of the $\overline{WE}$ signal. The only other timing constraints for a write-type-cycle is that both the $\overline{CAS}$ and $\overline{WE}$ signals remain in the logic 0 state for a sufficient time to accomplish the permanent storage of the data into the selected cell.

INPUT/OUTPUT LEVELS

All of the inputs to the MCM4027 are TTL-compatible, featuring high impedance and low capacitance (5 to 7 pF). The three-state data output buffer is TTL-compatible and has sufficient current sink capability (3.2 mA) to drive two TTL loads. The output buffer also has a separate V_{CC} pin so that it can be powered from the same supply as the logic being employed.

REFRESH

In order to maintain valid data, each of the 64 internal rows of the MCM4027 must be refreshed once every 2 ms. Any cycle in which a $\overline{RAS}$ signal occurs accomplishes a refresh operation. Any read, write, or read-modify-write cycle will refresh an entire internally selected row. However, if a write or read-modify-write cycle is used to perform a refresh cycle the chip must be deselected to prevent writing data into the selected cell. The memory can also be refreshed by employing only the $\overline{RAS}$ cycle. This refresh mode will not shorten the refresh cycle time, however the system standby power can be reduced by approximately 30%.

If the $\overline{RAS}$ only refresh cycles are employed for an extended length of time, the output buffer may eventually lose data and assume the high impedance state. Applying $\overline{CAS}$ to the chip will restore activity of the output buffer.

POWER DISSIPATION

Since the MCM4027 is a dynamic RAM, its power drain will be extremely small during the time the chip is unselected.

The power increases when the chip is selected and most of this increase is encountered on the address strobe edge. The circuitry of the MCM4027 is largely dynamic so power is not drawn during the whole time the strobe is active. Thus the dynamic power is a function of the operating frequency rather than the active duty cycle.

In a memory system, the $\overline{CAS}$ signal must be supplied to all the memory chips to ensure that the outputs of the unselected chips are switched to the high impedance state. Those chips that do not receive a $\overline{RAS}$ signal will not dissipate any power on the $\overline{CAS}$ edge except for that required to turn off the chip outputs. Thus, in order to ensure minimum system power, the $\overline{RAS}$ signal should be decoded so that only the chips to be selected receive a $\overline{RAS}$ signal. If the $\overline{RAS}$ signal is decoded, then the chip select input of all the chips can be set to a logic 0 state.

DC OPERATING CONDITIONS AND CHARACTERISTICS
(Full operating voltage and temperature range unless otherwise noted.)

RECOMMENDED OPERATING CONDITIONS (Referenced to V_{SS} = Ground.)

Parameter	Symbol	Min	Typ	Max	Unit	Notes
Supply Voltage	V_{DD}	10.8	12.0	13.2	Vdc	2
	V_{CC}	V_{SS}	5.0	V_{DD}	Vdc	3
	V_{SS}	0	0	0	Vdc	2
	V_{BB}	-4.5	-5.0	-5.5	Vdc	2
Logic 1 Voltage, $\overline{RAS}$, $\overline{CAS}$, $\overline{WRITE}$	V_{IHC}	2.4	5.0	7.0	Vdc	2, 4
Logic 1 Voltage, all inputs except $\overline{RAS}$, $\overline{CAS}$, $\overline{WRITE}$	V_{IH}	2.2	5.0	7.0	Vdc	2, 4
Logic 0 Voltage, all inputs	V_{IL}	-1.0	0	0.8	Vdc	2, 4

DC CHARACTERISTICS (V_{DD} = 12 V ±10%, V_{CC} = 5.0 V ±10%, V_{BB} = -5.0 V ±10%, V_{SS} = 0 V, T_A = 0 to 70°C.) Notes 1, 5

Characteristic	Symbol	Min	Typ	Max	Units	Notes
Average V_{DD} Power Supply Current	I_{DD1}			35	mA	6
V_{CC} Power Supply Current	I_{CC}				mA	7
Average V_{BB} Power Supply Current	I_{BB}			150	μA	
Standby V_{DD} Power Supply Current	I_{DD2}			2	mA	9
Average V_{DD} Power Supply Current during "$\overline{RAS}$ only" cycles	I_{DD3}			25	mA	6
Input Leakage Current (any input)	$I_{I(L)}$			10	μA	8
Output Leakage Current	$I_{O(L)}$			10	μA	9, 10
Output Logic 1 Voltage @ I_{out} = -5 mA	V_{OH}	2.4			Vdc	
Output Logic 0 Voltage @ I_{out} = 3.2 mA	V_{OL}			0.4	Vdc	

NOTES 1 through 11:

1. T_A is specified for operation at frequencies to $t_{RC} \geq t_{RC}(min)$. Operation at higher cycle rates with reduced ambient temperatures and higher power dissipation is permissible provided that all ac parameters are met.
2. All voltages referenced to V_{SS}.
3. Output voltage will swing from V_{SS} to V_{CC} when enabled, with no output load. For purposes of maintaining data in standby mode, V_{CC} may be reduced to V_{SS} without affecting refresh operations or data retention. However, the $V_{OH}(min)$ specification is not guaranteed in this mode.
4. Device speed is not guaranteed at input voltages greater than TTL levels (0 to 5 v).
5. Several cycles are required after power-up before proper device operation is achieved. Any 8 cycles which perform refresh are adequate for this purpose.
6. Current is proportional to cycle rate. $I_{DD1}(max)$ is measured at the cycle rate specified by $t_{RC}(min)$.
7. I_{CC} depends on output loading. During readout of high level data V_{CC} is connected through a low impedance (135 Ω typ) to Data Out. At all other times I_{CC} consists of leakage currents only.
8. All device pins at 0 volts except V_{BB} which is at -5 volts and the pin under test which is at +10 volts.
9. Output is disabled (high-impedance) and $\overline{RAS}$ and $\overline{CAS}$ are both at a logic 1. Transient stabilization is required prior to measurement of this parameter.
10. $0 V \leq V_{Out} \leq +10 V$.
11. Effective capacitance is calculated from the equation:

$$C = \frac{\Delta Q}{\Delta V} \text{ with } \Delta V = 3 \text{ volts.}$$

EFFECTIVE CAPACITANCE (Full operating voltage and temperature range, periodically sampled rather than 100% tested) Note 11

Characteristic		Symbol	Max	Unit
Input Capacitance	(A0-A5), D_{in}, $\overline{CS}$	$C_{in(EFF)}$	5.0	pF
	$\overline{RAS}$, $\overline{CAS}$, $\overline{WRITE}$		7.0	
Output Capacitance		$C_{out(EFF)}$	7.0	pF

$\overline{RAS}$ to $\overline{WRITE}$ Delay	t_{RWD}	110		145		175		ns	20

NOTES 12 through 20:

12. AC measurements assume t_T = 5 ns.

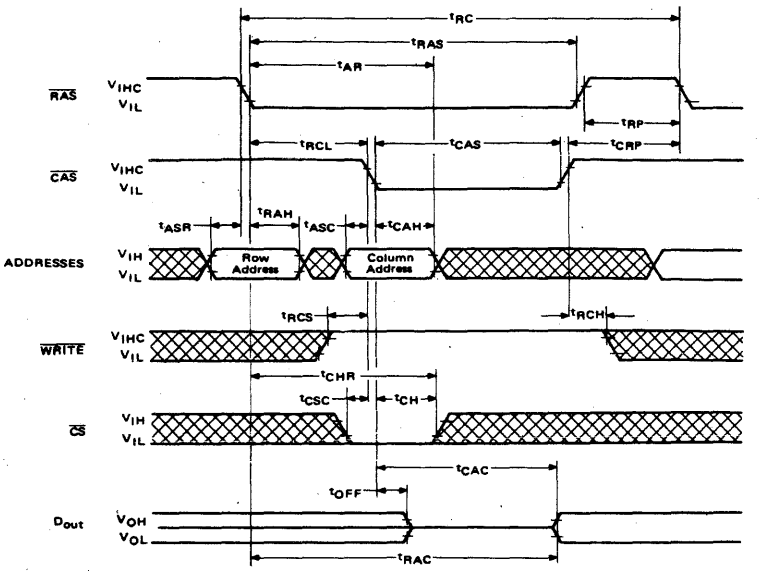
13. The specifications for t_{RC}(min) and t_{RWC}(min) are used only to indicate cycle time at which proper operation over the full temperature range (0°C ≤ T_A ≤ 70°C) is assured.

14. Assumes that $t_{RCD} \leq t_{RCD}$(max).

15. Assumes that $t_{RCD} \geq t_{RCD}$ (max).

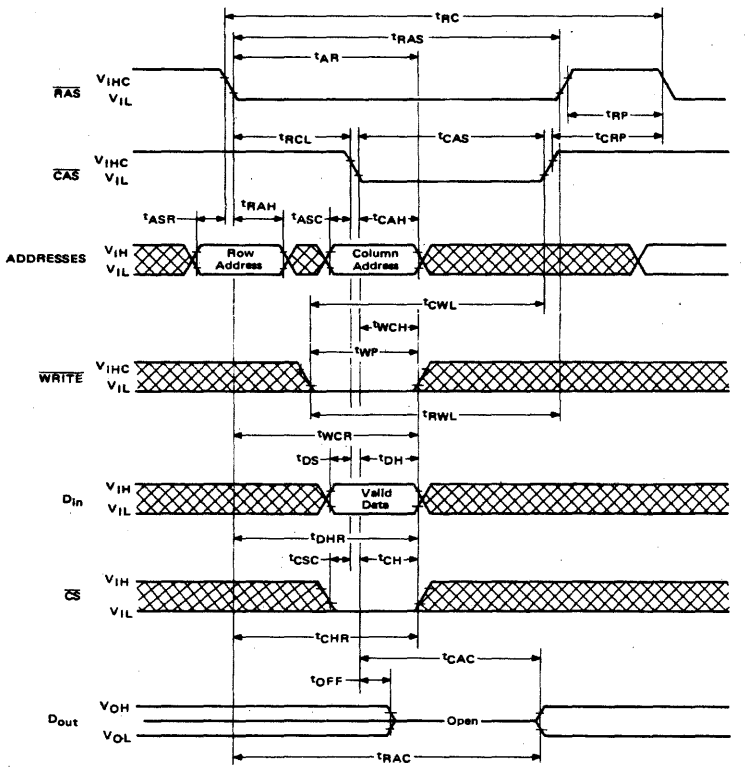
16. Measured with a load circuit equivalent to 2 TTL loads and 100 pF.

17. Operation within the t_{RCD}(max) limit insures that t_{RAC}(max) can be met. t_{RCD}(max) is specified as a reference point only; if t_{RCD} is greater than the specified t_{RCD}(max) limit, then access time is controlled exclusively by t_{CAC}.



18. V_{IHC}(min) or V_{IH}(min) and V_{IL}(max) are reference levels for measuring timing of input signals. Also, transition times are measured between V_{IHC} or V_{IH} and V_{IL}.

19. These parameters are referenced to $\overline{CAS}$ leading edge in random write cycles and to $\overline{WRITE}$ leading edge in delayed write or read-modify write cycles.



20. t_{WCS}, t_{CWD}, and t_{RWD} are not restrictive operating parameters. They are included in the data sheet as electrical characterisitcs only: If $t_{WCS} \geq t_{WCS}$(min), the cycle is an early write cycle and Data Out will contain the data written into the selected cell. If $t_{CWD} \geq t_{CWD}$(min) and $t_{RWD} \geq t_{RWD}$(min), the cycle is a read-write cycle and Data Out will contain data read from the selected cell. If neither of the above sets of conditions is satisfied, the condition of Data Out (at access time) is indeterminate.

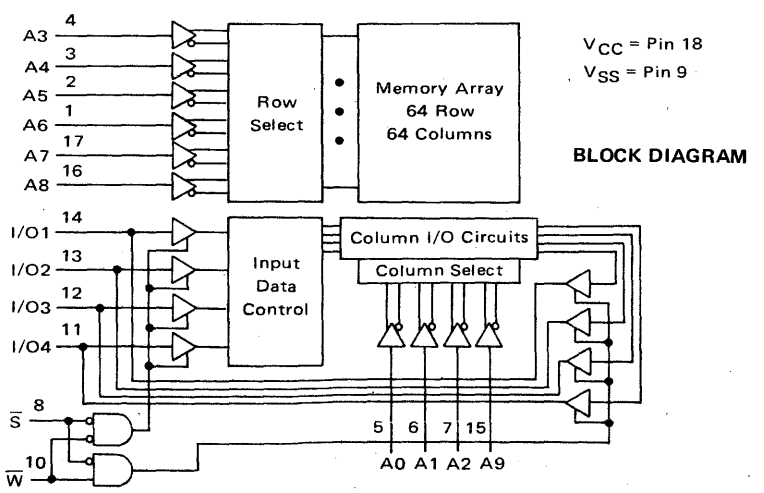
Advance Information

4096-BIT STATIC RANDOM ACCESS MEMORY

The MCM2114 is a 4096-bit random access memory fabricated with high density, high reliability N-channel silicon-gate technology. For ease of use, the device operates from a single power supply, is directly compatible with TTL and DTL, and requires no clocks or refreshing because of fully static operation. Data access is particularly simple, since address setup times are not required. The data out has the same polarity as the input data.



The MCM2114 is designed for memory applications where simple interfacing is the design objective. The MCM2114 is assembled in 18-pin dual in-line packages with the industry standard pin-out. A separate chip select ($\overline{S}$) lead allows easy selection of an individual package when the three-state outputs are OR-tied.

The MCM2114 series has a maximum power dissipation of 525 mW. Low power versions (i.e., MCM21L14 series) are available with a maximum power dissipation of only 370 mW.

- 1024 Words by 4-Bit Organization
- Industry Standard 18-Pin Configuration
- Single +5 Volt Supply ±10% Tolerance
- No Clock or Timing Strobe Required
- Fully Static: Cycle Time = Access Time
- Fully TTL/DTL Compatible
- Common Data Input and Output
- Three-State Outputs for OR-Ties
- Low Power Version Available — 370 mW (Max)

MAXIMUM ACCESS TIME/MINIMUM CYCLE TIME

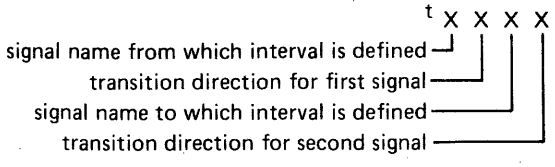
*130 mAdc for MCM6830A and MCM68A316A,

CAPACITANCE

(f = 1.0 MHz, T_A = 25°C, periodically sampled rather than 100% tested.)

Characteristic	Symbol	Max	Unit
Input Capacitance	C_{in}	7.5	pF
Output Capacitance	C_{out}	12.5	pF

AC OPERATING CONDITIONS AND CHARACTERISTICS



Read Cycle (64K only)

RECOMMENDED AC OPERATING CONDITIONS

(T_A = 0 to 70°C, V_{CC} = 5.0 V ± 10%. All timing with t_r = t_f = 20 ns, load of Figure 1.)

Parameter	Symbol	MCM68B364		MCM68A364		Unit
		Min	Max	Min	Max	
Address Valid to Address Don't Care (Cycle Time when Chip Enable is held Active)	t_{AVAX}	250	–	350	–	ns
Chip Enable Low to Chip Enable High	t_{ELEH}	250	–	350	–	
Address Valid to Output Valid (Access)	t_{AVQV}	–	250	–	350	
Chip Enable Low to Output Valid (Access)	t_{ELQV}	–	250	–	350	
Address Valid to Output Invalid	t_{AVQX}	10	–	10	–	
Chip Enable Low to Output Invalid	t_{ELQX}	10	–	10	–	
Chip Enable High to Output High Z	t_{EHQZ}	0	70	0	80	
Chip Selection to Power Up Time	t_{PU}	0	–	0	–	
Chip Deselection to Power Down Time	t_{PD}	–	100	–	120	
Address Valid to Chip Enable Low (Address Setup)	t_{AVEL}	0	–	0	–	

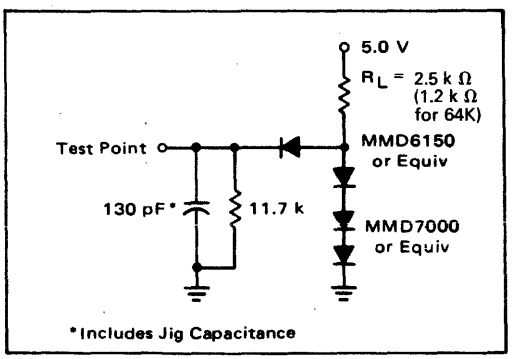
TIMING PARAMETER ABBREVIATIONS

The transition definitions used in this data sheet are:

- H = transition to high
- L = transition to low
- V = transition to valid
- X = transition to invalid or don't care
- Z = transition to off (high impedance)

©IC MASTER 1979

AC OPERATING CONDITIONS AND CHARACTERISTICS



(Full operating voltage and temperature unless otherwise noted.
All timing with $t_r = t_f = 20$ ns, Load of Figure 1)

Characteristic	Symbol	MCM68A308		MCM68B308		Unit
		Min	Max	Min	Max	
Cycle Time	t_{cyc}	350	–	250	–	ns
Access Time	t_{acc}	–	350	–	250	ns
Chip Select to Output Delay	t_{SO}	–	150	–	150	ns
Data Hold from Address	t_{DHA}	10	–	10	–	ns
Data Hold from Deselection	t_{DHD}	10	150	10	150	ns

TIMING LIMITS

The table of timing values shows either a minimum or a maximum limit for each parameter. Input requirements are specified from the external system point of view. Thus, address setup time is shown as a minimum since the system must supply at least that much time (even though most devices do not require it). On the other hand, responses from the memory are specified from the device point of view. Thus, the access time is shown as a maximum since the device never provides data later than that time.

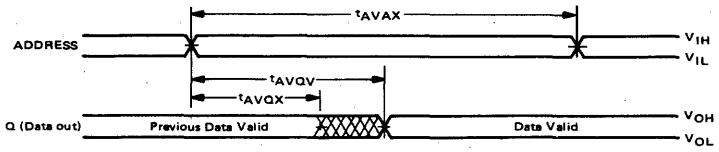
FIGURE 1 – AC TEST LOAD

WAVEFORMS

Waveform Symbol	Input	Output
———	MUST BE VALID	WILL BE VALID
———		
⟋⟋⟋	CHANGE FROM H TO L	WILL CHANGE FROM H TO L
⟋⟋⟋	CHANGE FROM L TO H	WILL CHANGE FROM L TO H
⟋⟋⟋	DON'T CARE: ANY CHANGE PERMITTED	CHANGING: STATE UNKNOWN
⟋⟋⟋	–	HIGH IMPEDANCE

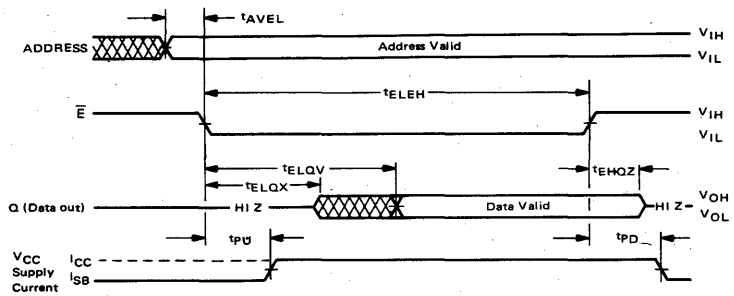
CUSTOM PROGRAMMING

By the programming of a single photomask for the MCM68/MCM68 family, the customer may specify the content of the memory and the method of enabling the outputs.



Information on the general options of the MCM68/MCM68 family should be submitted on an Organizational Data form such as that shown in Figure 3.

Information for custom memory content may be sent to Motorola in one of two forms (shown in order of preference):



1. IBM Punch Cards
   A. Hexadecimal Format
   B. INTEL Hexadecimal Format
   C. Binary Negative-Positive Format
2. EPROMs – four 16K (MCM2716, or TMS2716, or eight 8K (MCM2708).

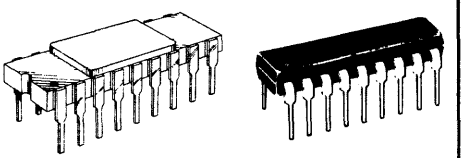
CMOS LSI
(LOW-POWER COMPLEMENTARY MOS)

1024 X 1 BIT STATIC RANDOM ACCESS MEMORY

1024 X 1 BIT STATIC RANDOM ADDRESS MEMORY



The MCM146508 and MCM146518 are fully static 1024 X 1 RAMS fabricated using high performance silicon gate CMOS technology. They offer low-power operation from a single 5.0 V supply with data retention to 2.0 V. The MCM146508 has the two select lines and the enable line brought out as a single enable line.

- Low Standby and Operating Power
- Single 5.0 V Supply
- Data Retention to 2.0 V
- Fast Access Time
- Address Latches
- Three-State Outputs
- Fully TTL Compatible Inputs/Outputs
- Fully Static Operation
- Direct Replacement for
  Harris HM6508/HM6518
  Intersil IM6508/IM6518

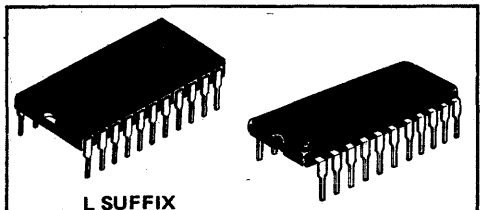
MCM145101

256 X 4 BIT STATIC RAM

The MCM145101 family of CMOS RAMs offers ultra low power and fully static operation with a single 5 volt supply. The CMOS 1024-bit devices are organized in 256 words by 4 bits. Separate data inputs and data outputs permit maximum flexibility in bus-oriented systems. Data retention at a power supply as low as 2.0 volts over temperature readily allows design into applications using battery backup for nonvolatility. The MCM145101 is fully static and does not require clocking in standby mode.



The MCM145101 is fabricated using the Motorola advanced ion-implanted, silicon-gate technology for high performance and high reliability.

- Low Standby Power
- Fast Access Time
- Single + 5.0 Volt Supply
- Fully TTL Compatible—All Inputs and Outputs
- Three-State Output
- Fully Static Operation
- Data Retention to 2.0 Volts
- Direct Replacement for:
  - Intel 5101 Series
  - AMI S5101 Series
  - Hitachi MH435101 Series
- Pin Replacement for Harris HM6501 Series

Future Memory Technology Development

National Semiconductor
Thomas Klein*
January 1978

ABSTRACT: Semiconductor integrated circuit based memory devices became the dominant Random Access Memory technology in less than 8 years. They were able to achieve this because their batch manufacturing process allowed a very rapid reduction of cost per bit of storage through technological changes to increase batch density. Continued progress in density improvement at essentially unchanged rates is still feasible. It will, however, require major changes in manufacturing, device and material technology.

Since the beginning of the 70's, semiconductor integrated circuits used as digital storage elements have become a very significant factor in the total spectrum of information storage technology. They became the dominant technology for random access memories and are beginning to make inroads into the slower serial access memory market, presently dominated by magnetic discs and drums.

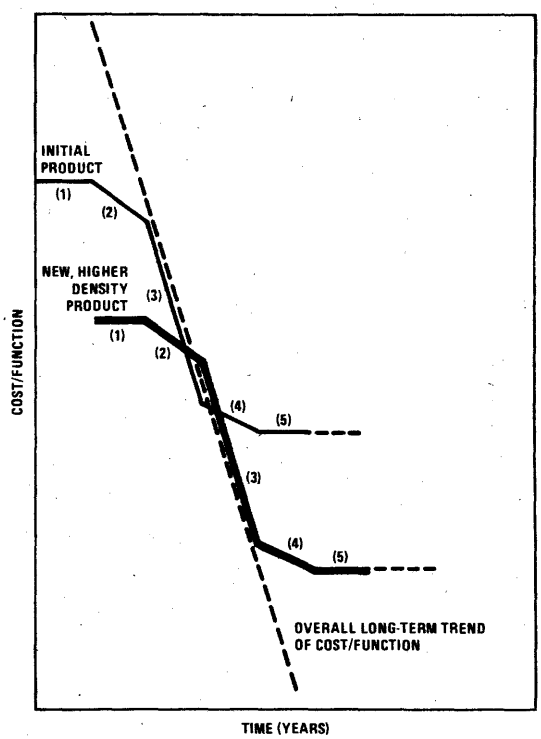
The ability of integrated circuit technology to continue to offer digital data storage at very rapidly decreasing cost per bit of storage is a consequence of the batch manufacturing process. It allows introductions of new products which are cost effective even at very low manufacturing efficiency level, obtain very steep cost reduction during product life by rapid increase of manufacturing efficiency and continue to stay on the steep cost reduction curve by going to a higher level of integration when cost improvements through improved manufacturing efficiencies are starting to flatten out.

However, to go to a higher level of integration, which in case of Random Access Memory circuits, usually means a four-fold increase in number of bits on the chip, a significant improvement in batch density is required, otherwise no benefit is derived *(Figure 1)*.

This batch density (i.e., number of potentially good storage elements processed together as a single unit (i.e., a silicon wafer) has shown an even higher rate of growth than the much more visible increase in the number storage bits/memory circuit.

During the past eight years the number of potentially good storage elements contained on a single silicon wafer has risen from about 50,000 to over 6 million, with the cost of processing a wafer rising only very slowly and manufacturing efficiency expressed as the percentage of good units staying level or improving slightly.

Future progress in memory technology can be examined in terms of this single variable common to all present and future solid state memory technologies.



There are several technological trends that are unfolding right now which are likely to impact future memory technology developments.

These trends can be classified under the following categories:

a. Continued evolutionary process of memory cost reduction through more advanced circuit and device design techniques and improved process and manufacturing efficiencies.

b. A significant change in device and circuit sizes through major changes in pattern definition technology and an electrical scaling of devices to take advantage of the size reduction.

c. Charge Coupled Device and Magnetic Bubble Domain device based memory technologies.

NOTES:
(1) Product is introduced, very little or no competition.
(2) Product is multiple sourced but prices still hold up as production is limited.
(3) Production expands dramatically as yields improve, competition is fierce, prices tumble, marginal suppliers are beginning to drop out.
(4) Significant yield improvements are no longer available, new product is beginning to compete for the same market, competition is still intense, suppliers still drop out.
(5) Major market share is taken by new generation of product, market shrinks but prices hold up as competition is minimal.

FIGURE 1. Typical Decrease of Memory Products' Prices/Costs During Product Life

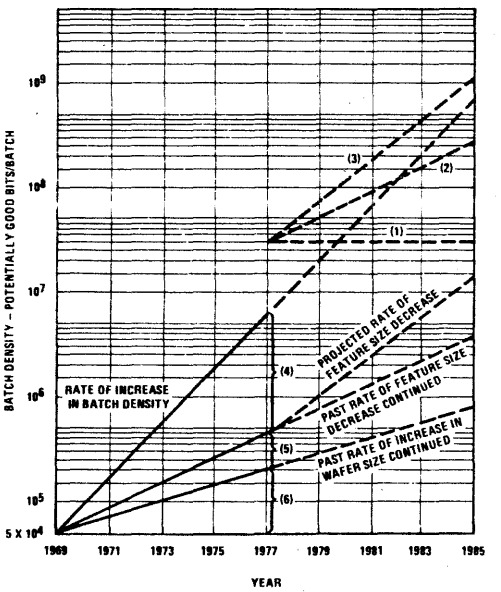
"TURN TO PAGES 270-285 FOR FULL APPLICATION NOTE"

©IC MASTER 1979

a. EVOLUTIONARY PROCESS

This approach has so far been the most successful and continued improvements may still be expected. In fact, as long as this is a viable path for future development, it is likely to be the most vigorously pursued approach.



In terms of its future potential, we might examine past contributions to batch density improvements.

The total batch density improvement of 120-fold in eight years was contributed by:

1. Higher bit density through design and process innovation: 13.5x
2. Larger wafer area: 4x
3. Smaller feature sizes and tighter alignment tolerances: 2.2x

Continued improvement based on comparable contributions from the same sources is no longer feasible for the following reasons:

Design and process improvements, the most profitable source of past batch density improvement, is getting sufficiently close to its theoretical limits so that progress in it is likely to slow down *(Figure 2)*. It is clear that regardless of whatever technique we use to design or build a memory cell, it must have at least 2 features in both x and y directions, one to store the information and one to separate it from the adjacent cell. This defines a theoretical minimum cell size of 4 f^2 where f is the minimum feature size determined by the limits of pattern definition technology.

NOTES:
(1) Theoretical limit, current wafer and feature sizes.
(2) Theoretical limit, assuming continued improvements in wafer size increase and feature size reduction.
(3) Theoretical limit, assuming constant rate of wafer size increase and an *increasing* rate of feature size reduction.
(4) Increase due to design and process innovations.
(5) Increase due to feature size improvement.
(6) Increase due to wafer size.

FIGURE 2. Past and Projected Contributions to Batch Density Improvements

Cell size eight years ago was a rich 200 f^2 leaving plenty of room for improvement. Today's cell size of 20 f^2 or less is sufficiently close to the theoretical limit of 4 f^2 that we can no longer project a rate of improvement comparable to past norms. We will do extremely well if we can extract a further 3-fold improvement.

Wafer size improvement will continue at an essentially constant rate. Wafer size increases are important not only for increased productivity, but wafer size is strongly correlated to maximum economically manufacturable die size *(Figure 3)*. Wafer diameter has been increasing at a rate of about 1.4 times every four years. This rate of increase is tied not only to the rate at which equipment manufacturers can develop new tooling to handle the larger wafer size, but also to the rate at which capital is invested in the semiconductor industry.

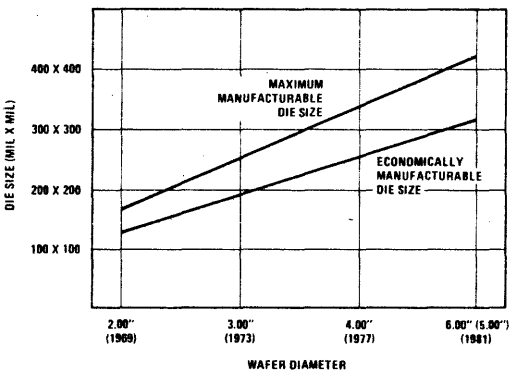


FIGURE 3. Maximum and Economic Die Size as a Function of Wafer Diameter (Time)

Feature size reduction. While we expect significant progress in this area, little of it can be considered evolutionary. In the past, progress in this area was completely evolutionary; contributing relatively little to density improvement. In the next 5 to 10 years we expect major changes in the technology and we will discuss those changes in detail later.

We also expect that manufacturing yields will increase in the next 5 to 10 years. This will be a factor in cost reduction but not in density.

The reason for yield improvement is the expected reduction in the rate of density improvement due to design and process improvements. Present manufacturing yields which include losses in wafer manufacturing, die sort, assembly and final test vary from under 5% for a leading edge product to about 25% for a mature product.

In the past, as long as significant density improvements were available from design and process innovations, engineering effort and talent was better utilized in trying to improve a new high density product's yield from 5% to 25%. Trying to extract the yield improvement available between 25% and 50%–60% which is

©IC MASTER 1979

probably the practical upper limit for any semiconductor product, was both harder and less rewarding. With less potential improvement available from design and process innovations, we can probably expect higher overall yields for mature products.

In summary, the evolutionary trend, while it will still contribute significantly to future cost reductions, its contribution will be proportionately less than it has been in the past.

b. FEATURE SIZE IMPROVEMENT

Minimum feature size has been remarkably stable over the past 20 years of integrated circuit technology development. This was probably due to the fact that there was very little change in pattern definition technology. Up to 1975 the pattern definition technology, at least at wafer level, was basically unchanged from what it was in the late 50's and progress was obtained by better engineering, controlling and understanding the process and using improved photochemical materials.

Maskmaking technology made much more consistent progress, converting from an essentially manual drafting to a completely computerized pattern definition process.

Since the mid-70's, very significant changes are beginning to occur at wafer level too. Availability and acceptance of *projection aligners* is the first and probably the most significant of these changes.

Their introduction did not lead to an immediate reduction in feature size, but the control, reproducibility and accuracy of mask dimensions that they allow, makes feature size reduction a much more realistic task.

Improved high resolution photoresists are also becoming available.

Dry etching techniques are important technological achievements and will also be contributing to feature size reduction.

Electron beam and X-ray lithography are the most frequently mentioned technologies to achieve significant reductions in feature size.

There is undoubtedly significant progress being made in these areas and some of the results are impressive. However, they have to overcome some very significant technical and economic hurdles before they can make an impact on memory technology *(Figure 4)*.

Electron beam writing techniques are already available for maskmaking purposes where they offer some very real advantages. For direct writing on wafers, however, they still have to improve significantly and come down in price before they can make an impact on memory technology. Presently, projected machine costs and throughput times are such that processing wafers with electron beam writing instead of conventional masking—assuming no other technical problems—would raise wafer processing cost by a factor of 5. This cost increase would take care of all cost reduction achieved by the smaller feature size at *equal yield*. Since the smaller feature size means more densely built circuits sensitive to much smaller defect sizes the most immediate consequence of feature size reduction is yield reduction.

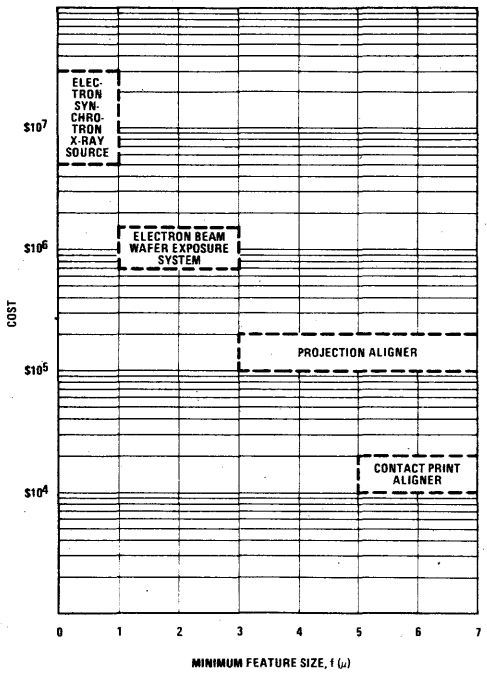

FIGURE 4. Cost of Key Equipment for Various Pattern Definition Technologies and Minimum Feature Sizes

X-ray lithography techniques have still to resolve three basic problems.

a. Maskmaking technology

b. Sufficiently intensive X-ray sources

c. Pattern registration

If they can solve these problems, they can be potentially very powerful as they can use a fixed mask and do not have to regenerate the entire pattern at every exposure.

Summarizing present status of pattern definition technologies, we can project improvements in optical pattern definition technology to yield a 5 to 8-fold increase in batch density over the next 5 to 8 years. This will represent a 2.5 to 4-fold increase in the rate of progress compared to past experience. Even higher rates of progress are possible if electron beam and/or X-ray lithography matures sufficiently to become cost effective, over the next 5 to 8 years.

Electrical Scaling of Devices

In the previous discussion, we have made the implicit assumption that feature size reduction is equivalent to circuit area reduction.

This is most certainly not the case. Feature size reduction will merely define limits to circuit size reduction. The actual reduction available will be determined by how closely the electrical device and circuit characteristics allow us to approach the limits imposed by pattern definition technology.

©IC MASTER 1979

All three presently used major memory technologies (i.e., MOS dynamic, MOS static and bipolar static) are more limited by device and circuit design considerations, rather than optical pattern resolution.

In case of MOS devices, their performance is a function of the operating voltages and their ability to handle high operating voltages decreases very rapidly with reduced device sizes. Consequently, if denser memory circuits were to be built by taking advantage of feature size reduction, the operating voltages will have to be reduced. The resulting device and circuit performance reduction can be regained by re-engineering the entire device, reducing oxide thickness, junction depth and increasing substrate doping to make the device deliver an equivalent performance at lower operating voltages.

This total re-engineering of device structure, processing and manufacturing technology is called "scaling" and it is obviously a major engineering and manufacturing task, involving all aspects of wafer technology.

Bipolar memory circuits do not appear to suffer from this limitation; their's is, however, a different one. Device sizes can be reduced but their density cannot be significantly increased, because current drain of a bipolar device does not scale with size. Consequently, any attempt to take advantage of reduced device size by increasing number of bits/chip will run into severe power dissipation limits. Again the problem is technically solvable at an expense of major circuit design/process re-engineering efforts to "current scale" bipolar device/process technology.

I^2L technology appears technically attractive from this point of view (i.e., it would be able to take advantage of feature size reduction with the least amount of device and/or process engineering changes). Its problem is that it has so far not been able to establish a sufficiently attractive price/performance combination to gain a significant position in the memory market.

Feature size reduction and the required electrical scaling of devices will have some very important consequences in terms of relative impact on various memory technologies. When we scale devices, we adjust some basic device parameters and operating voltages so as to obtain as nearly identical device and circuit characteristics as possible. This can be achieved quite successfully for the type of circuits whose design is by and large based on the device characteristics that we have scaled (i.e., MOS static devices). For these devices, reduction of supply voltage also brings about a reduction in power dissipation, so one limitation to higher density, characteristic of static devices has also been removed.

MOS dynamic circuits which have traditionally enjoyed a 4:1 density advantage over static devices, rely more on second order effects like leakage currents, subthreshold conduction and signal to noise ratio in their sense amplifier designs, do not benefit quite as readily from scaling.

Leakage current, whose relation to stored charge is vitally important to the successful operation of MOS dynamic random access memory circuits, does not scale proportionately with voltage, due the point defect nature of the leakage current. Typically any junction's leakage current represents a spatial averaging over a relatively large number of defects. Reducing junction area will increase fluctuation in number of defect sites from one storage area to the next. Since dynamic RAM design imposes requirement that *all* storage areas have less than certain pre-determined amount of leakage current, scaling will typically reduce ratio of stored charge to leakage current. Since the signal available is already reduced by both scaling and the resulting increase in density, designers of future generation of dynamic RAM's face some formidable challenges. It is possible that the only way they will be able to overcome these challenges is to impose very strict environmental limitations on the finished product, namely cooling or even refrigeration of memory systems.

Feature size reduction and electrical scaling will impose some very stringent demands on process engineering in terms of both control and the degree of perfection required for good yields from the scaled structures. We are assuming that these problems are solvable by evolutionary improvements in processing techniques. We should not be surprised, however, if progress in those areas from time to time fails to keep up with the more visible improvements available from pattern definition technology.

c. NEW TECHNOLOGIES

Success in semiconductor integrated circuit based random access memory technology prompted considerable interest in solid state replacements for serial memories. The two most often considered candidates are Charge Coupled Devices and Bubble Domain Memory devices.

Charge Coupled Devices represent the densest silicon based technology we know. However, their speed and ease of use is considerably inferior to random access memories and as long as random access memories can be made with comparable circuit density, C.C.D. is hard pressed to carve out a market position. Typically, for a C.C.D. circuit to be competitive with RAMs, it has to offer a 4:1 density advantage over a comparably sized RAM circuit. So far it has not been able to do it, partly because RAM technology very quickly adopted all process improvements made for C.C.D. circuits and used them to make competitively sized RAMs.

However, C.C.D. technology is expected to establish a 4:1 density advantage over RAMs in the reasonably near future because its technology and organization permits:

a. Approaching the theoretical minimum storage area of 4 f^2 both more easily and more closely than RAMs.

b. Meeting the challenges of feature size reduction and device scaling more easily than dynamic RAM's.

Several features of C.C.D. technology contribute to these advantages. Absence of P-N junctions allows storage and transfer functions to be very similar structurally and either very closely spaced, or used interchangeably for both functions.

Although charge is stored dynamically, it is not held at any location for longer than a clock cycle so effect of

©IC MASTER 1979

defect density fluctuation is averaged out over a large area. Signal strength is comparable to RAM's but there is more flexibility in sense amplifier design. Absence of contacts and P-N junctions allows more efficient layout and easier scaling of devices.

Bubble Memory Technology

Although both its device and material technology is significantly different from silicon integrated circuits, it is also based on a batch manufacturing process with the cost of a function very strongly dependent of the functional density per batch and manufacturing yields.

Examined from this point of view, it has some very major disadvantages coupled with some even greater potential long-term benefits.

First of all, as a device it is very well suited to serial storage of data. Although it is slower than any silicon I.C. based storage circuit, it is non-volatile—or at least it can be designed to be—and it can also be used to perform very simple logic functions which allow data to be stored and retrieved efficiently. Also, it can be used to pre-amplify the otherwise very small signal magnetically so it can be used to design a reasonably self-contained memory chip.

Its known major disadvantages are:

1. Very high material cost, caused by both very high initial substrate cost and a very costly, difficult and low productivity liquid phase epitaxy deposition process. Material cost is 30—50 times higher than silicon.
2. Very high packaging cost. Every circuit has to have an individually adjusted bias field and a rotating magnetic field built into the package.
3. A batch density which is presently not significantly higher than what is achievable with silicon.

Set against these disadvantages we can consider the potential long-term benefits which motivate the ever increasing activity in the field:

1. Processing typically requires only 3 masking steps, only one of which is critical, compared to 6+ for silicon.
2. Although present bit density is not impressive, it is based on a relatively simple design with bit area being in the 200 f^2 region for a T bar configuration, indicating very much room for improvement, some of which has already been implemented experimentally.
3. Because it has only one critical masking step and no critical alignment requirements, it is the technology best positioned to take advantage of improvements in pattern definition techniques.

It is difficult today to determine the point both in time and in level of complexity at which Bubble Memory Devices will be able to enter the market and compete successfully. But once they do, they will enjoy a very rapid growth comparable to silicon integrated circuit based memory circuits for exactly the same reasons.

Summarizing these trends, there is sufficient visibility for the continued technical progress of memory technology at essentially unchanged rates for the next 5 to 8 years.

One word of caution, however, is worth mentioning here. The key to past success and the continued objective of memory technology development is *cost reduction*.

Technical developments to continue to increase density of memory circuits are worthwhile only if they can make a significant contribution to this overall objective. They cannot do it if the cost of improvement is so high that it swallows up all future cost benefits.

Even if their cost is less than potential cost reduction benefit, they still represent a very significant investment in design, process development, production and testing facilities and product start-up costs for the component manufacturer.

Such an investment will only be economically attractive if the market for memory products continues to expand at a fast rate.

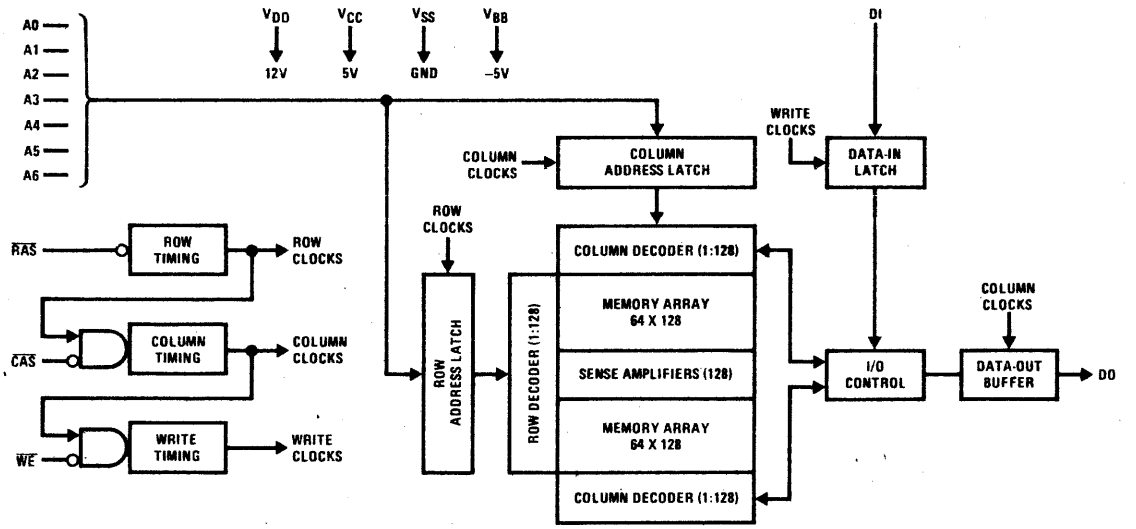
National Semiconductor

MOS RAMs

MM5290 16,384-Bit (16,384 × 1) Dynamic RAM

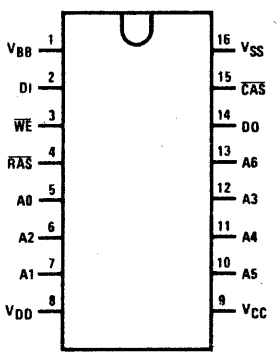
General Description

The MM5290 is a 16,384 x 1 bit dynamic RAM. It features a multiplexed address input with separate row and column strobes. This added flexibility allows the MM5290 to be used in page mode operation.



The MM5290 must be refreshed every 2 ms. This can be accomplished by performing any cycle which brings the Row Address Strobe active including a $\overline{RAS}$-only cycle at each of the 128 row addresses.

N-channel double-poly silicon gate technology, developed by National, is used in the manufacture of the MM5290. This process combines high density and performance with reliability. Greater system densities are achievable by the use of a 16-pin dual-in-line package for the MM5290.



Features

- Access times: 150 ns, 200 ns, 250 ns
- Low power: 528 mW max
- TTL compatible: all inputs and output
- Gated $\overline{CAS}$—noncritical timing
- Read, Write, Read-Modify-Write and $\overline{RAS}$-only Refresh cycles
- Page mode operation
- Industry standard 16-pin configuration

Note 1: "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. Except for "Operating Temperature Range" they are not meant to imply that the devices should be operated at these limits. The table of "Recommended DC Operating Conditions" provides conditions for actual device operation.

Note 2: All voltages referenced to V_{SS}. When applying voltages to the device, V_{DD}, V_{CC} or V_{SS} should never be 0.3V more negative than V_{BB}.

Note 3: Several cycles are required after power-up before proper device operation is achieved. Any 8 RAS cycles are adequate for this purpose.

Note 4: I_{DD1}, I_{DD3}, and I_{DD4} depend on cycle rate.

Note 5: I_{CC} depends on output load.

Note 6: Capacitance measured with Boonton Meter or effective capacitance calculated from the equation $C = I\Delta t/\Delta V$. Capacitance is guaranteed by periodic testing.

t_{RWD}	$\overline{RAS}$ to $\overline{WE}$ Delay	120		160		200		ns	15

Note 7: The specifications for $t_{RC(MIN)}$ and $t_{RWC(MIN)}$ are used only to indicate cycle time at which proper operation over the full temperature range is guaranteed.

Note 8: Transition times are measured between V_{IHC} or V_{IH} and V_{IL}. Timing measurements are made between $V_{IHC(MIN)}$ or $V_{IH(MIN)}$ and $V_{IL(MAX)}$, and assume t_T = 5 ns.

Note 9: Assumes row-limited access, i.e., $t_{RCD} \leq t_{RCD(MAX)}$. If this condition is not satisfied, then note 10 applies.

Note 10: Assumes column-limited access, i.e., $t_{RCD} > t_{RCD(MAX)}$.

Note 11: Equivalent load is 2 standard TTL inputs plus 100 pF.

Note 12: $\overline{CAS}$ going high disables the Data Output. t_{OFF} is the delay to the high impedance state.

Note 13: These parameters are referenced to the negative edge of $\overline{CAS}$ in an early-write cycle and to the negative edge of $\overline{WE}$ in a Read-Modify-Write cycle. (See Note 12, below).

Note 14: If $t_{WCS} \geq t_{WCS(MIN)}$, the Data Output is guaranteed to remain in the high impedance state for the duration of the cycle. This is the "early-write" cycle.

Note 15: If $t_{CWD} \geq t_{CWD(MIN)}$ and $t_{RWD} \geq t_{RWD(MIN)}$, the Data Output will contain the original data in the selected cell. This is the Read-Modify-Write cycle. If either of these conditions is not satisfied, the output will be indeterminate unless the early-write condition of Note 12 is met.

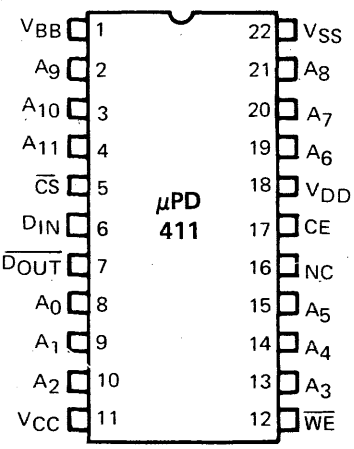
FULLY DECODED RANDOM ACCESS MEMORY

DESCRIPTION

The μPD411 Family consists of six 4096 words by 1 bit dynamic N-channel MOS RAMs. They are designed for memory applications where very low cost and large bit storage are important design objectives. The μPD411 Family is designed using dynamic circuitry which reduces the standby power dissipation.

Reading information from the memory is a non-destructive. Refreshing is easily accomplished by performing one read cycle on each of the 64 row addresses. Each row address must be refreshed every two milliseconds. The memory is refreshed whether Chip Select is a logic high or a logic low.

FEATURES



All of these products are guaranteed for operation over the 0 to 70°C temperature range.

Important features of the μPD411 family are:

- Low Standby Power
- 4096 words x 1 bit Organization
- A single low-capacitance high level clock input with solid ±1 volt margins.
- Inactive Power/0.3 mW (Typ.)
- Power Supply: +12, +5, -5V
- Easy System Interface
- TTL Compatible (Except CE)
- Address Registers on the Chip
- Simple Memory Expansion by Chip Select
- Three State Output and TTL Compatible
- 22 pin Ceramic Dual-in-Line Package
- Replacement for INTEL'S 2107B, TI'S 4060 and Equivalent Devices.
- 4 Performance Ranges:

	ACCESS TIME	R/W CYCLE	RMW CYCLE	REFRESH TIME
μPD411-E	350 ns	800 ns	960 ns	1 ms
μPD411	300 ns	470 ns	650 ns	2 ms
μPD411-1	250 ns	470 ns	640 ns	2 ms
μPD411-2	200 ns	400 ns	520 ns	2 ms
μPD411-3	150 ns	380 ns	470 ns	2 ms
μPD411-4	135 ns	320 ns	320 ns	2 ms

PIN CONFIGURATION

PIN NAMES

FUNCTIONAL DESCRIPTION

CE Chip Enable

A single external clock input is required. All read, write, refresh and read-modify-write operations take place when chip enable input is high. When the chip enable is low, the memory is in the low power standby mode. No read/write operations can take place because the chip is automatically precharging.

$\overline{CS}$ Chip Select

The chip select terminal affects the data in, data out and read/write inputs. The data input and data output terminals are enabled when chip select is low. The chip select input must be low on or before the rising edge of the chip enable and can be driven from standard TTL circuits. A register for the chip select input is provided on the chip to reduce overhead and simplify system design.

$\overline{WE}$ Write Enable

The read or write mode is selected through the write enable input. A logic high on the $\overline{WE}$ input selects the read mode and a logic low selects the write mode. The $\overline{WE}$ terminal can be driven from standard TTL circuits. The data input is disabled when the read mode is selected.

A_0–A_{11} Addresses

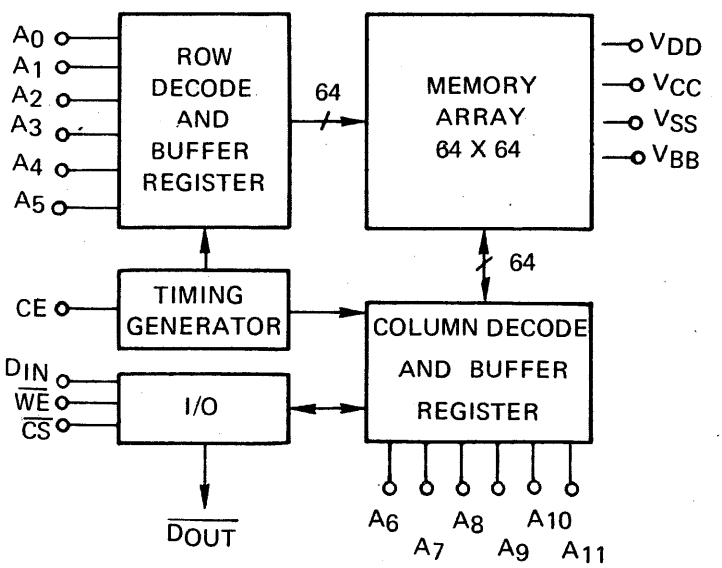
All addresses must be stable on or before the rising edge of the chip enable pulse. All address inputs can be driven from standard TTL circuits. Address registers are provided on the chip to reduce overhead and simplify system design.

D_{IN} Data Input

Data is written during a write or read-modify-write cycle while the chip enable is high. The data in terminal can be driven from standard TTL circuits. There is no register on the data in terminal.

$\overline{D_{OUT}}$ Data Output

The three state output buffer provides direct TTL compatibility with a fan-out of two TTL gates. The output is in the high-impedance (floating) state when the chip enable is low or when the Chip Select input is high. Data output is inverted from data in.



Refresh

Refresh must be performed every two milliseconds by cycling through the 64 addresses of the lower-order-address inputs A_0 through A_5 or by addressing every row within any 2*-millisecond period. Addressing any row refreshes all 64 bits in that row.

The chip does not need to be selected during the refresh. If the chip is refreshed during a write mode, the chip select must be high.

*μPD411-E = 1 millisecond refresh period.

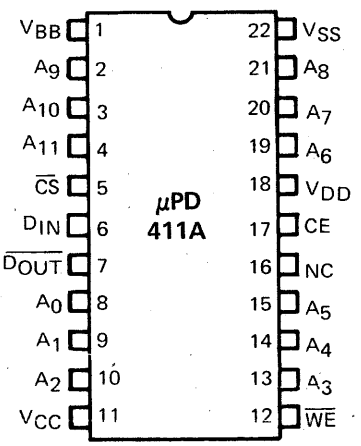
4096 BIT DYNAMIC RAMS

DESCRIPTION

The μPD411A Family consists of four 4096 words by 1 bit dynamic N-channel MOS RAMs. They are designed for memory applications where very low cost and large bit storage are important design objectives. The μPD411A Family is designed using dynamic circuitry which reduces the standby power dissipation.



Reading information from the memory is non-destructive. Refreshing is easily accomplished by performing one read cycle on each of the 64 row addresses. Each row address must be refreshed every two milliseconds. The memory is refreshed whether Chip Select is a logic high or a logic low.

FEATURES

- Low Standby Power
- 4096 words x 1 bit Organization
- A single low-capacitance high level clock input with solid ±1 volt margins.
- Inactive Power 0.7 mW (Typ.)
- Power Supply +12, +5, −5V
- Easy System Interface
- TTL Compatible (Except CE)
- Address Registers on the Chip
- Simple Memory Expansion by Chip Select
- Three State Output and TTL Compatible
- 22 pin Plastic or Cerdip Dual-in-Line Package
- Replacement for INTEL's 2107B, TI's 4060 and Equivalent Devices.
- 4 Performance Ranges:

	ACCESS TIME	R/W CYCLE	RMW CYCLE	REFRESH TIME
μPD411A-E	350 ns	800 ns	960 ns	1 ms
μPD411A	300 ns	470 ns	650 ns	2 ms
μPD411A-1	250 ns	430 ns	600 ns	2 ms
μPD411A-2	200 ns	400 ns	520 ns	2 ms

PIN CONFIGURATION

PIN NAMES

A_0 - A_{11}	Address Inputs
A_0 - A_5	Refresh Addresses
CE	Chip Enable
$\overline{CS}$	Chip Select
D_{IN}	Data Input
$\overline{D_{OUT}}$	Data Output
$\overline{WE}$	Write Enable
V_{DD}	Power (+12V)
V_{CC}	Power (+5V)
V_{SS}	Ground
V_{BB}	(Powe. −5V)
NC	No Connection

©IC MASTER 1979

FUNCTIONAL DESCRIPTION

CE Chip Enable

A single external clock input is required. All read, write, refresh and read-modify-write operations take place when chip enable input is high. When the chip enable is low, the memory is in the low power standby mode. No read/write operations can take place because the chip is automatically precharging.

$\overline{CS}$ Chip Select

The chip select terminal affects the data in, data out and read/write inputs. The data input and data output terminals are enabled when chip select is low. The chip select input must be low on or before the rising edge of the chip enable and can be driven from standard TTL circuits. A register for the chip select input is provided on the chip to reduce overhead and simplify system design.

$\overline{WE}$ Write Enable

The read or write mode is selected through the write enable input. A logic high on the $\overline{WE}$ input selects the read mode and a logic low selects the write mode. The $\overline{WE}$ terminal can be driven from standard TTL circuits. The data input is disabled when the read mode is selected.

A_0–A_{11} Addresses

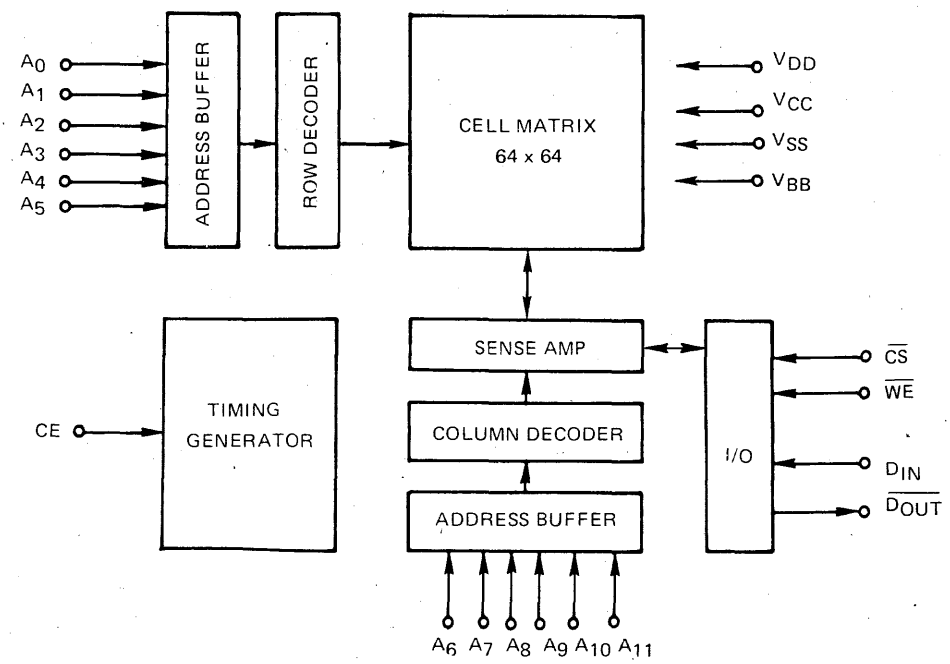
All addresses must be stable on or before the rising edge of the chip enable pulse. All address inputs can be driven from standard TTL circuits. Address registers are provided on the chip to reduce overhead and simplify system design.

D_{IN} Data Input

Data is written during a write or read-modify-write cycle while the chip enable is high. The data in terminal can be driven from standard TTL circuits. There is no register on the data in terminal.

$\overline{D_{OUT}}$ Data Output

The three state output buffer provides direct TTL compatibility with a fan-out of two TTL gates. The output is in the high-impedance (floating) state when the chip enable is low or when the Chip Select input is high. Data output is inverted from data in.



Refresh

Refresh must be performed every two milliseconds by cycling through the 64 addresses of the lower-order-address inputs A_0 through A_5 or by addressing every row within any 2*-millisecond period. Addressing any row refreshes all 64 bits in that row.

The chip does not need to be selected during the refresh. If the chip is refreshed during a write mode, the chip select must be high.

*μPD411A-E = 1 millisecond refresh period.

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	0°C to +70°C
Storage Temperature	−55°C to +150°C
Output Voltage ①	+20 to −0.3 Volts
All Input Voltages ①	+20 to −0.3 Volts
Supply Voltage V_{DD} ①	+20 to −0.3 Volts
Supply Voltage V_{CC} ①	+20 to −0.3 Volts
Supply Voltage V_{SS} ①	+20 to −0.3 Volts
Power Dissipation	1.0W

Note: ① Relative to V_{BB}.

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

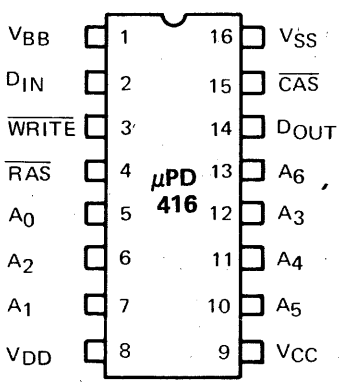
16384 x 1 BIT DYNAMIC MOS RANDOM ACCESS MEMORY

DESCRIPTION

The NEC μPD416 is a 16384 words by 1 bit Dynamic MOS RAM. It is designed for memory applications where very low cost and large bit storage are important design objectives.

The μPD416 is fabricated using a double-poly-layer N channel silicon gate process which affords high storage cell density and high performance. The use of dynamic circuitry throughout, including the sense amplifiers, assures minimal power dissipation.



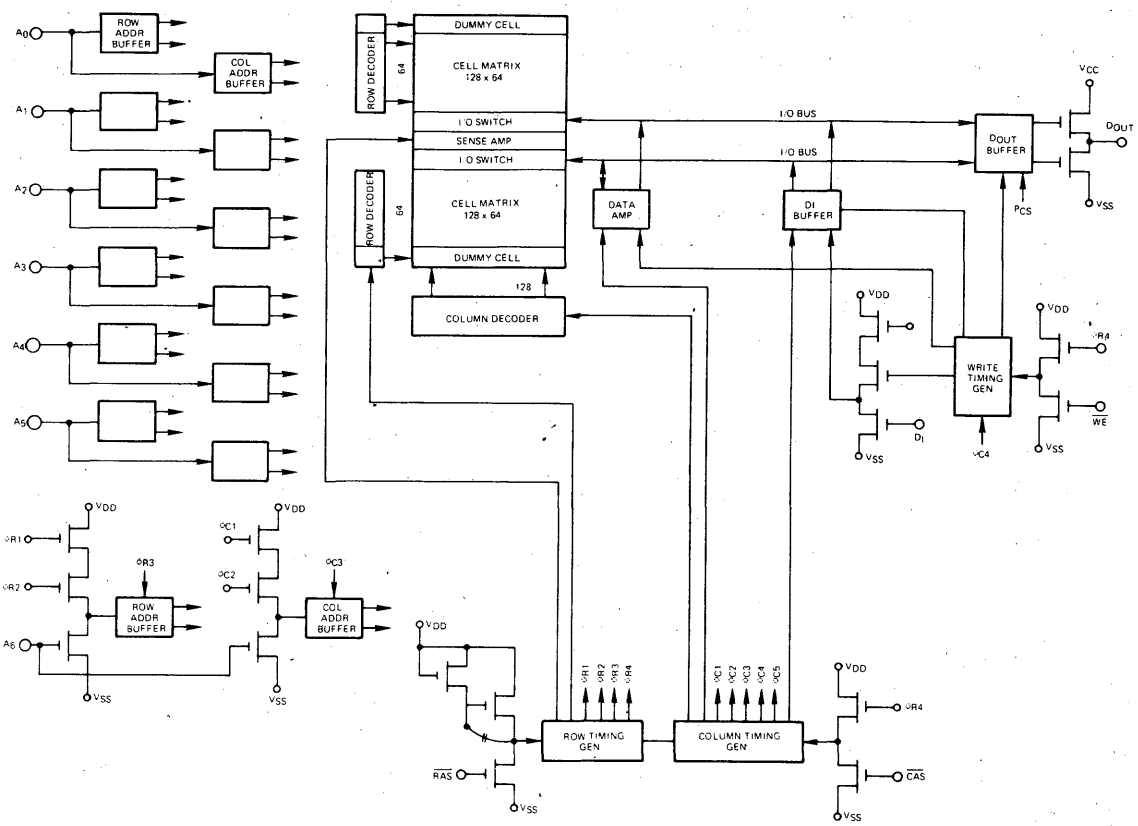
Multiplexed address inputs permit the μPD416 to be packaged in the standard 16 pin dual-in-line package. The 16 pin package provides the highest system bit densities and is available in either ceramic or plastic. Noncritical clock timing requirements allow use of the multiplexing technique while maintaining high performance.

FEATURES

- 16384 Words x 1 Bit Organization
- High Memory Density – 16 Pin Ceramic and Plastic Packages
- Multiplexed Address Inputs
- Standard Power Supplies +12V, -5V, +5V
- Low Power Dissipation; 462 mW Active (MAX), 40 mW Standby (MAX)
- Output Data Controlled by $\overline{CAS}$ and Unlatched at End of Cycle
- Read-Modify-Write, $\overline{RAS}$-only Refresh, and Page Mode Capability
- All Inputs TTL Compatible, and Low Capacitance
- 128 Refresh Cycles
- 5 Performance Ranges:

	ACCESS TIME	R/W CYCLE	RMW CYCLE
μPD416	300 ns	510 ns	575 ns
μPD416-1	250 ns	410 ns	465 ns
μPD416-2	200 ns	375 ns	375 ns
μPD416-3	150 ns	375 ns	375 ns
μPD416-5	120 ns	320 ns	320 ns

PIN CONFIGURATION



A_0-A_6	Address Inputs
$\overline{CAS}$	Column Address Strobe
D_{IN}	Data In
D_{OUT}	Data Out
$\overline{RAS}$	Row Address Strobe
$\overline{WRITE}$	Read/Write
V_{BB}	Power (-5V)
V_{CC}	Power (+5V)
V_{DD}	Power (+12V)

Output High Voltage (Logic 1)	V_{OH}	2.4			V	I_{OUT} = −5 mA (3)
Output Low Voltage (Logic 0)	V_{OL}			0.4	V	I_{OUT} = 4.2 mA

Notes: (1) T_a is specified here for operation at frequencies to $t_{RC} \geq t_{RC}$ (min). Operation at higher cycle rates with reduced ambient temperatures and high power dissipation is permissible, however, provided AC operating parameters are met. See Figure 1 for derating curve.

(2) All voltages referenced to V_{SS}.

(3) Output voltage will swing from V_{SS} to V_{CC} when activated with no current loading. For purposes of maintaining data in standby mode, V_{CC} may be reduced to V_{SS} without affecting refresh operations or data retention. However, the V_{OH} (min) specification is not guaranteed in this mode.

(4) I_{DD1}, I_{DD3}, and I_{DD4} depend on cycle rate. See Figures 2, 3 and 4 for I_{DD} limits at other cycle rates.

(5) I_{CC1} and I_{CC4} depend upon output loading. During readout of high level data V_{CC} is connected through a low impedance (135Ω typ) to data out. At all other times I_{CC} consists of leakage currents only.

DERATING CURVES

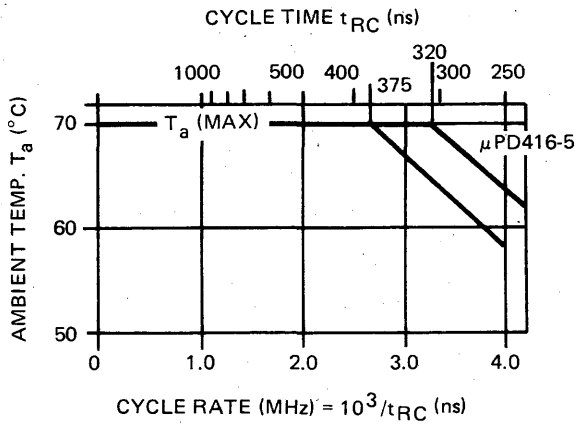

FIGURE 1

Maximum ambient temperature versus cycle rate for extended frequency operation. T_a (max) for operation at cycling rates greater than 2.66 MHz (t_{CYC} < 375 ns) is determined by T_a (max) [°C] = 70 – 9.0 x (cycle rate [MHz] –2.66). For μPD416-5, it is T_a (max) [°C] = 70 – 9.0 (cycle rate [MHz] – 3.125).

$\overline{CAS}$ to $\overline{WRITE}$ delay	t_{CWD}	140		125		95		70		80		ns	⑩
$\overline{RAS}$ to $\overline{WRITE}$ delay	t_{RWD}	240		200		160		120		120		ns	⑩

Notes:
① AC measurements assume t_T = 5 ns.
② V_{IHC} (min) or V_{IH} (min) and V_{IL} (max) are reference levels for measuring timing of input signals. Also, transition times are measured between V_{IHC} or V_{IH} and V_{IL}.
③ The specifications for t_{RC} (min) and t_{RWC} (min) are used only to indicate cycle time at which proper operation over the full temperature range (0°C ≤ T_a ≤ 70°C) is assured.
④ Assumes that $t_{RCD} \leq t_{RCD}$ (max). If t_{RCD} is greater than the maximum recommended value shown in this table, t_{RAC} will increase by the amount that t_{RCD} exceeds the values shown.
⑤ Assumes that $t_{RCD} \geq t_{RCD}$ (max).
⑥ Measured with a load equivalent to 2 TTL loads and 100 pF.
⑦ t_{OFF} (max) defines the time at which the output achieves the open circuit condition and is not referenced to output voltage levels.
⑧ Operation within the t_{RCD} (max) limit ensures that t_{RAC} (max) can be met, t_{RCD} (max) is specified as a reference point only, if t_{RCD} is greater than the specified t_{RCD} (max) limit, then access time is controlled exclusively by t_{CAC}.
⑨ These parameters are referenced to $\overline{CAS}$ leading edge in early write cycles and to $\overline{WRITE}$ leading edge in delayed write or read-modify-write cycles.
⑩ t_{WCS}, t_{CWD} and t_{RWD} are not restrictive operating parameters. They are included in the data sheet as electrical characteristics only. If $t_{WCS} \geq t_{WCS}$ (min), the cycle is an early write cycle and the data out pin will remain open circuit (high impedance) $\geq t_{RWD}$ (min), the cycle is a read-write cycle and the data out will contain data read from the selected cell; if neither of the above sets of conditions is satisfied the condition of the data out (at access time) is indeterminate.

ADDRESSING

The 14 address bits required to decode 1 of 16,384 bit locations are multiplexed onto the 7 address pins and then latched on the chip with the use of the Row Address Strobe ($\overline{RAS}$), and the Column Address Strobe ($\overline{CAS}$). The 7 bit row address is first applied and $\overline{RAS}$ is then brought low. After the $\overline{RAS}$ hold time has elapsed, the 7 bit column address is applied and $\overline{CAS}$ is brought low. Since the column address is not needed internally until a time of t_{CRD} MAX after the row address, this multiplexing operation imposes no penalty on access time as long as $\overline{CAS}$ is applied no later than t_{CRD} MAX. If this time is exceeded, access time will be defined from $\overline{CAS}$ instead of $\overline{RAS}$.

DATA I/O

For a write operation, the input data is latched on the chip by the negative going edge of $\overline{WRITE}$ or $\overline{CAS}$, whichever occurs later. If $\overline{WRITE}$ is active before $\overline{CAS}$, this is an "early WRITE" cycle and data out will remain in the high impedance state throughout the cycle. For a READ, WRITE, OR READ-MODIFY-WRITE cycle, the data output will contain the data in the selected cell after the access time. Data out will assume the high impedance state anytime that $\overline{CAS}$ goes high.

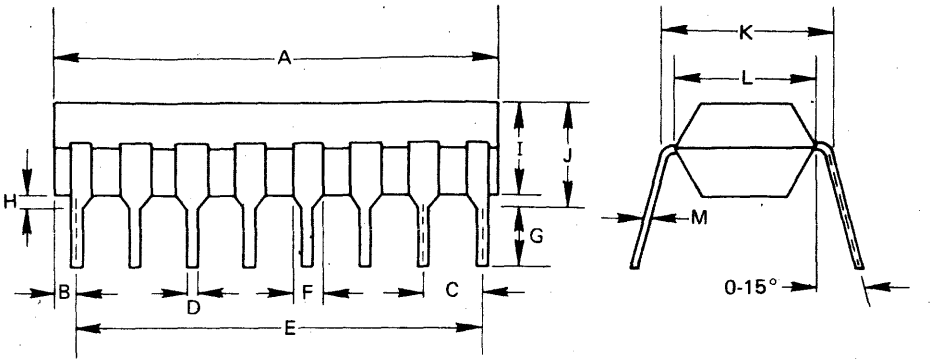
PAGE MODE

The page mode feature allows the μPD416 to be read or written at multiple column addresses for the same row address. This is accomplished by maintaining a low on $\overline{RAS}$ and strobing the new column addresses with $\overline{CAS}$. This eliminates the setup and hold times for the row address resulting in faster operation.

REFRESH

Refresh of the memory matrix is accomplished by performing a memory cycle at each of the 128 row addresses every 2 milliseconds or less. Because data out is not latched, "$\overline{RAS}$ only" cycles can be used for simple refreshing operation.

CHIP SELECTION



Either $\overline{RAS}$ and/or $\overline{CAS}$ can be decoded for chip select function. Unselected chip outputs will remain in the high impedance state.

POWER SEQUENCING

In order to assure long term reliability, V_{BB} should be applied first during power up and removed last during power down.

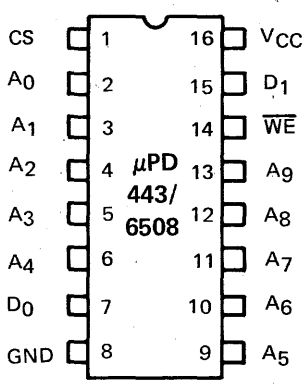
PRELIMINARY

1024 BIT CMOS RANDOM ACCESS MEMORY

DESCRIPTION



The μPD443/6508 is a high speed, low power, silicon gate CMOS 1024 bit static RAM organized as 1024 words by 1 bit. In all static states this RAM exhibits the microwatt power requirements typical of CMOS.

Inputs and three state output are TTL compatible. The basic part operates at 4 to 7 volts with a +5V, 25°C access time of 200 ns and supply current of 100 μA. Data retention is guaranteed to 3V on all parts.

FEATURES

- Low Power Operation
- Excellent Speed Operation
- TTL Compatible on Inputs and Outputs
- Static Operation
- On-Chip Address Register
- Replacement for IM 6508 and Equivalent Devices
- Available in Standard 16 Pin Ceramic Package

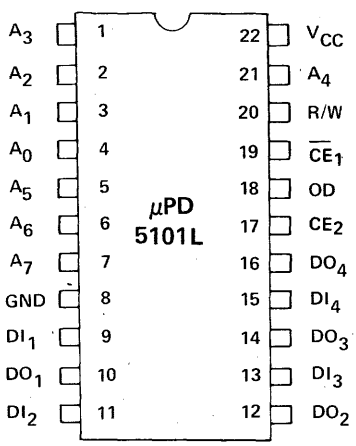
1024 BIT (256x4) STATIC CMOS RAM

DESCRIPTION

The μPD5101L and μPD5101L-1 are very low power 1024 bit (256 words by 4 bits) static CMOS Random Access Memories. They meet the low power requirements of battery operated systems and can be used to ensure non-volatility of data in systems using battery backup power.

All inputs and outputs of the μPD5101L and μPD5101L-1 are TTL compatible. Two chip enables ($\overline{CE}_1$, CE_2) are provided, with the devices being selected when $\overline{CE}_1$ is low and CE_2 is high. The devices can be placed in standby mode, drawing 10 μA maximum, by driving $\overline{CE}_1$ high and inhibiting all address and control line transitions. The standby mode can also be selected unconditionally by driving CE_2 low.



The μPD5101L and μPD5101L-1 have separate input and output lines. They can be used in common I/O bus systems through the use of the OD (Output Disable) pin and OR-tying the input/output pins. Output data is the same polarity as input data and is nondestructively read out. Read mode is selected by placing a high on the R/W pin. Either device is guaranteed to retain data with the power supply voltage as low as 2.0 volts. Normal operation requires a single +5 volt supply.

The μPD5101L and μPD5101L-1 are fabricated using NEC's silicon gate complementary MOS (CMOS) process.

FEATURES

- Directly TTL Compatible – All Inputs and Outputs
- Three-State Output
- Access Time – 650 ns (μPD5101L); 450 ns (μPD5101L-1)
- Single +5V Power Supply
- CE_2 Controls Unconditional Standby Mode
- Available in a 22-pin Dual-in-Line Package

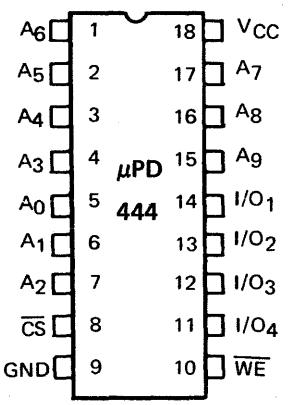
4K STATIC CMOS RAM



DESCRIPTION

The μPD444 is a 4K Static CMOS RAM, organized as 1K x 4. Its use of CMOS technology assures extremely low operating and standby power requirements.

FEATURES

- Compatible with 2114L
- Single +5V Supply
- Fully Static — No Clocks
- 300 ns Access Time

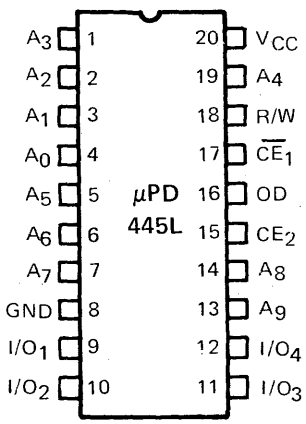
PIN CONFIGURATION

©IC MASTER 1979

FULLY DECODED 4096 STATIC CMOS RAM

DESCRIPTION

The μPD445L is a very low power 4,096 bit (1024 words by 4 bits) static RAM fabricated with NEC's complementary MOS (CMOS) process. It has two chip enable inputs ($\overline{CE}_1$, CE_2). Minimum standby current is drawn when $\overline{CE}_1$ is at a high level, while inhibiting all address and control line transitions or, unconditionally when CE_2 is at a low level. This device ideally meets the low power requirements of battery operated systems and battery back-up systems for non-volatility of data.



The μPD445L uses fully static circuitry requiring no clocking. Output data is read out non-destructively by placing a high on the R/W pin and has the same polarity as input data. All inputs and outputs are directly TTL compatible. The device has common input/output data busses and an OD (Output Disable) pin for use in common I/O bus systems.

The μPD445L is guaranteed to retain data with the power supply voltage as low as 2.0 volts.

FEATURES

- Single +5V Power Supply
- Ideal for Battery Operation
- Low Standby Power for Data Retention
- Simple Memory Expansion – Chip Enable Inputs
- Access Time – 650 ns Max. (μPD445L)
  450 ns Max. (μPD445L-1)
- Directly TTL Compatible – All Inputs and Outputs
- Common Data Input and Output
- Static CMOS – No Clocks Refreshing Required
- 20 Pin Dual-In-Line Plastic Package

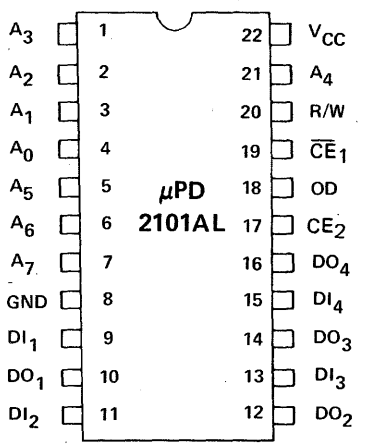
μPD2101AL
μPD2101AL-2
μPD2010AL-4

1024 BIT (256 X 4) STATIC MOS RAM WITH SEPARATE I/O

DESCRIPTION

The μPD2101AL is a 256 word by 4 bit static random access memory requiring no clocks or refreshing. It features high speed, low cost, and simplicity of interfacing.

It is directly TTL compatible in all respects; inputs, outputs, and a single +5V supply. Two chip-enables allow easy selection of an individual package when outputs are OR-tied. An output disable is provided so that data inputs and outputs can be tied for common I/O systems. The output disable function eliminates the need for bidirectional logic in a common I/O system. Output data is the same polarity as input data, and readout is non-destructive.



The μPD2101AL family of devices offers access times from 450 ns to 250 ns with a typical standby mode power dissipation of only 36 mW.

The use of NEC's N-channel silicon gate MOS process, with its excellent protection from contamination, permits the use of a low cost 22 pin plastic package in providing a high performance, high reliability MOS circuit at a most cost effective price level. The μPD2101AL is pin-compatible with the μPD5101 CMOS static RAM.

FEATURES

- 256 x 4 Organizations to Meet Needs for Small System Memories
- Access Time – 250 to 450 nsec max
- Directly TTL Compatible – All Inputs and Output
- Static MOS – No Clocks or Refreshing Required
- Simple Memory Expansion – Chip Enable Input
- Low Standby Power – 36 mW typ.
- Low Cost Packaging – 22 Pin Plastic Dual-In-Line Configuration
- Low Operating Power
- Three-State Output – OR-Tie Capability
- Output Disable Provided for Ease of Use in Common Data Bus Systems

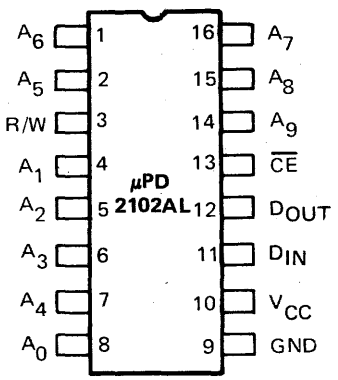
1024 BIT FULLY DECODED STATIC MOS RANDOM ACCESS MEMORY

DESCRIPTION

The μPD2102AL is a 1024 words by one bit static Random Access Memory requiring no clocks or refreshing. A family of devices with maximum access times ranging from 250 ns to 450 ns meet the requirements of microcomputer memory applications where speed, low cost and easy interfacing are prime design objectives.



All μPD2102AL inputs and outputs are TTL compatible. A single chip-enable ($\overline{CE}$) pin is provided for selection of an individual device in systems with OR-tied outputs. Output data is the same polarity as input data and is nondestructively read out. Only a single +5 volt supply is required. In standby mode, with the supply lowered to 1.5 volts, power dissipation is reduced to 42 mW max.

The μPD2102AL family is fabricated using NEC's N-channel MOS silicon gate process, providing excellent contamination protection. This process permits the use of a low cost plastic package (16 pin) and enables high performance, highly reliable MOS circuits to be produced.

FEATURES

- Access Time – μPD2102AL-2 – 250 ns Max
  μPD2102AL – 350 ns Max
  μPD2102AL-4 – 450 ns Max
- Single +5 Volts Supply Voltage
- Directly TTL Compatible – All Inputs and Output
- Static MOS – No Clocks or Refreshing Required
- Low Power – Typically 150 mW
- Low Standby Power – 42 mW max
- Three-State Output – OR-TIE Capability
- Simple Memory Expansion – Chip Enable Input
- Fully Decoded – On Chip Address Decode
- Inputs Protected – All Inputs have Protection against Static Charge
- Low Cost Packaging – 16 Pin Plastic Dual-In-Line Configuration

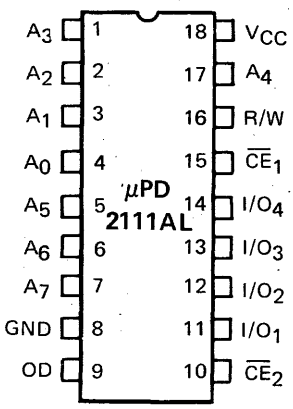
1024 BIT (256 x 4) STATIC MOS RAM WITH COMMON I/O AND OUTPUT DISABLE

DESCRIPTION

The μPD2111AL is a 256 words by 4 bits static random access memory fabricated with N-channel MOS technology. It uses fully static circuitry and therefore requires no clocks or refreshing to operate. The data is read out nondestructively and has the same polarity as the input data. Common input/output pins are provided.



It is directly TTL compatible in all respects: inputs, outputs, and a single +5V supply. Separate chip enable ($\overline{CE}$) leads allow easy selection of an individual package when outputs are OR-tied.

All members in the μPD2111AL family feature a low standby power mode with the supply voltage being reduced to +1.5V.

FEATURES

- 256 Words x 4 Bits Organization
- Common Data Input and Output
- Single +5V Supply Voltage
- Directly TTL Compatible — All Inputs and Outputs
- Static MOS — No Clocks or Refreshing Required
- Access Time — 250 ns to 450 ns max.
- Simple Memory Expansion — Chip Enable Inputs
- Fully Decoded — On Chip Address Decode
- Inputs Protected — All Inputs have Protection Against Static Charge
- Low Cost Packaging — 18 Pin Plastic Dual-In-Line Configuration
- Three-State Output — OR-Tie Capability
- Low Standby Power

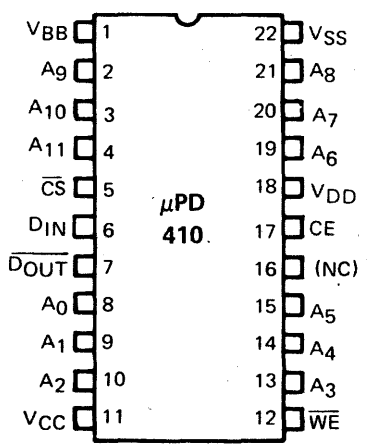
4096 BIT HIGH SPEED STATIC MOS RANDOM ACCESS MEMORY

DESCRIPTION

The μPD410 is a very high speed 4K bit static random access memory. It is organized as 4096 words by 1 bit per word and fabricated using N channel silicon gate MOS technology.



All signals to the device are TTL compatible except for Chip Enable which is standard +12 Volt MOS level.

Circuit operation starts with the rising edge of CE. Data is latched and valid until falling edge of CE. Address and Chip Select signals are latched on-chip to simplify system timing requirements.

FEATURES

- 4096 Words x 1 Bit Organization
- Fully Decoded
- TTL Compatible (except CE)
- High Speed-Access Time: 80 ns max.
- Cycle Time: 220 ns min.
- Static Operation — No Refresh Required
- Standby Power: 75 mW max.
- Active Power: 470 mW typ.
- Supply Voltages: V_{DD} = +12V, V_{CC} = +5V, V_{BB} = -5V
- Address Registers on the Chip
- Three State Output
- Standard 22 Pin Ceramic Dual-in-Line Package
- Pin Compatible with μPD411 and Other 4K Dynamic RAMs

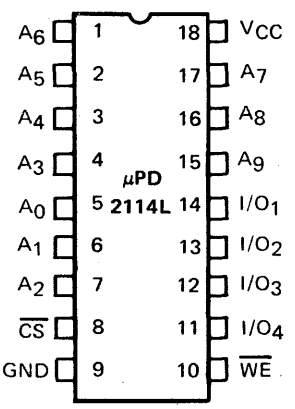
4096 BIT (1024 × 4 BITS) STATIC RAM

DESCRIPTION

The NEC μPD2114L is a 4096 bit static Random Access Memory organized as 1024 words by 4 bits using N-channel Silicon-gate MOS technology. It uses fully DC stable (static) circuitry throughout, in both the array and the decoding, and therefore requires no clocks or refreshing to operate and simplify system design. The data is read out nondestructively and has the same polarity as the input data. Common input/output pins are provided.



The μPD2114L is designed for memory applications where high performance, low cost, large bit storage, and simple interfacing are important design objectives. The μPD2114L is placed in an 18-pin package for the highest possible density.

It is directly TTL compatible in all respects: inputs, outputs, and a single +5V supply. A separate Chip Select ($\overline{CS}$) lead allows easy selection of an individual package when outputs are OR-Tied.

FEATURES

- Access Time: Selection from 250-450 ns
- Single +5 Volt Supply
- Directly TTL Compatible — All Inputs and Outputs
- Completely Static — No Clock or Timing Strobe Required
- Low Operating Power — Typically 0.06 mW/Bit
- Identical Cycle and Access Times
- Common Data Input and Output using Three-State Output
- High Density 18-pin Plastic and Ceramic Packages
- Replacement for 2114L and Equivalent Devices

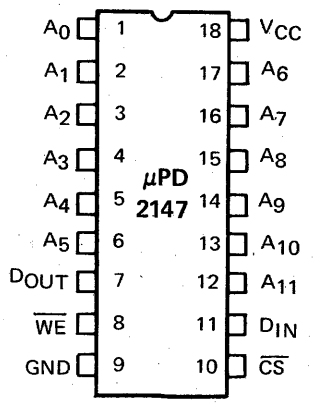
PRELIMINARY

4096 BIT HIGH SPEED STATIC RAM



DESCRIPTION

The μPD2147 is a very high speed, fully static, NMOS RAM, organized as 4096 x 1. It is available in an 18 pin dual-in-line package.

FEATURES

- Extremely High Speed, −55 ns (μPD2147-3)
- Single +5V Supply
- Fully Static — No Clocking Required
- Automatic Power-Down
- Fully TTL Compatible

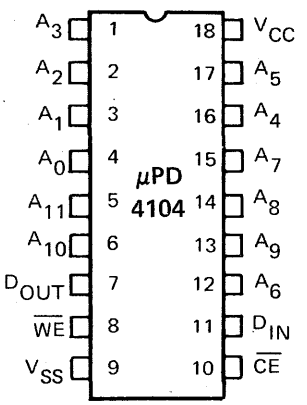
PRELIMINARY

4096 x 1 STATIC NMOS RAM

DESCRIPTION



The μPD4104 is a high performance 4K static RAM. Organized as 4096 x 1, it uses a combination of static storage cells with dynamic input/output circuitry to achieve high speed and low power in the same device. Utilizing NMOS technology, the μPD4104 is fully TTL compatible and operates with a single +5V ± 10% supply.

FEATURES

- Fast Access Time – 85 ns (μPD4104-36)
- Very Low Stand-By Power – 25 mW Max.
- Low V_{CC} Data Retention Mode to +3 Volts
- Single +5V ± 10% Supply
- Fully TTL Compatible
- Available in 18 Pin Plastic and Ceramic Dual-in-Line Packages
- 5 Performance Ranges:

	ACCESS TIME	R/W CYCLE	SUPPLY CURRENT	
			ACTIVE	STANDBY
μPD4104-30	300 ns	460 ns	21 mA	5 mA

Notes: ① All voltages referenced to V_{SS}.

② During power up, $\overline{CE}$ and $\overline{WE}$ must be at V_{IH} for minimum of 2 ms after V_{CC} reaches 4.5V, before a valid memory cycle can be accomplished.

③ Measured with load circuit equivalent to 2 TTL loads and CL = 100 pF.

④ If $\overline{WE}$ follows $\overline{CE}$ by more than t_{WS} then data out may not remain open circuited.

⑤ Determined by user. Total cycle time cannot exceed t_{CE} max.

⑥ Data-in set-up time is referenced to the later of the two falling clock edges $\overline{CE}$ or $\overline{WE}$.

⑦ AC measurements assume t_T = 5 ns. Timing points are taken as V_{IL} = 0.8V and V_{IH} = 2.2V on the inputs and V_{OL} = 0.4V and V_{OH} = 2.4V on the output waveform.

⑧ $t_C = t_{CE} + t_P + 2\,t_T$.

⑨ The true level of the output in the open circuit condition will be determined totally by output load conditions. The output is guaranteed to be open circuit within t_{OFF}.

⑩ $t_{RMW} = t_{AC} + t_{WPL} + t_P + 3\,t_T + t_{MOD}$.

READ CYCLE

WRITE CYCLE

READ-MODIFY-WRITE CYCLE

©IC MASTER 1979

OPERATIONAL DESCRIPTION

READ CYCLE

The selection of one of the possible 4096 bits is made by virtue of the 12 address bits presented at the inputs. These are latched into the chip by the negative going edge of chip enable ($\overline{CE}$). If the write enable ($\overline{WE}$) input is held at a high level (V_{IH}) while the $\overline{CE}$ input is clocked to a low level (V_{IL}), a read operation will be performed. At the access time (t_{AC}), valid data will appear at the output. Since the output is unlatched by a positive transition of $\overline{CE}$, it will be in the high impedance state from the previous cycle until the access time. It will go to the high impedance state again at the end of the current cycle when $\overline{CE}$ goes high.

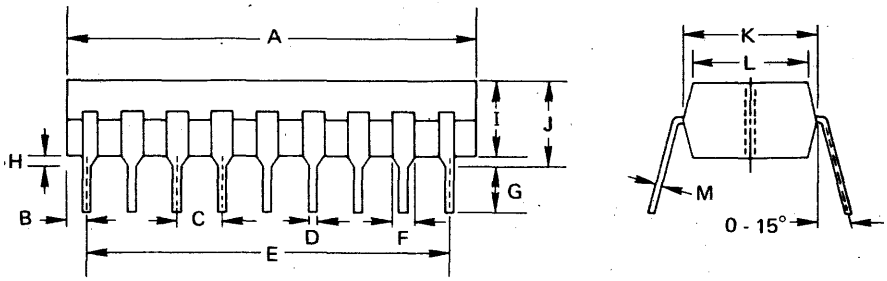
The address lines may be set up for the next cycle any time after the address hold time has been satisfied for the current cycle.

WRITE CYCLE

Data to be written into a selected cell is latched into the chip by the later negative transition of $\overline{CE}$ or WE. If $\overline{WE}$ is brought low before $\overline{CE}$, the cycle is an "Early Write" cycle, and data will be latched by $\overline{CE}$. If $\overline{CE}$ is brought low before $\overline{WE}$, as in a Read-Modify-Write cycle, then data will be latched by $\overline{WE}$. Two independent timing parameters must be satisfied for the data-in hold time; t_{DHI} and t_{DHC}. When the cycle is a R/W or R-M-W, t_{DHC} will be automatically satisfied. For a write cycle, both parameters must be paid attention to.

If the cycle is an "Early Write" cycle, the output will remain in the high impedance state. For a Read-Modify-Write cycle; the output will be active for the Modify and Write portions of the memory cycle until $\overline{CE}$ goes high. If $\overline{WE}$ is brought low after $\overline{CE}$ but before the access time, the state of the output will be undefined. The desired data will be written into the cell if data-in is valid on the leading edge of $\overline{WE}$, t_{DHI} and t_{DHC} are satisfied, and $\overline{WE}$ occurs prior to $\overline{CE}$ going high by at least the minimum lead time (t_{WPL}).

READ-MODIFY-WRITE



Read and Write cycles can be combined to allow reading of a selected location and then modifying that data within the same memory cycle. Data is read at the access time and modified during a period defined by the user. New data is written between $\overline{WE}$ low and the positive transition of $\overline{CE}$. Data out will remain valid until the rising edge of $\overline{CE}$. A minimum R-M-W cycle time can be calculated by $t_{RMW} = t_{AC} + t_{MOD} + t_{WPL} + t_P + 3\,t_T$; where t_{RMW} is the cycle time, t_{AC} is the access time, t_{MOD} is the user defined modify time, t_{WPL} is the $\overline{WE}$ to $\overline{CE}$ lead time, t_P is the $\overline{CE}$ high time, and t_T is one transition time.

POWER DOWN MODE

In power down, data may be retained indefinitely by maintaining V_{CC} at +3V. However, prior to V_{CC} going below V_{CC} minimum ($\leqslant$4.5V) $\overline{CE}$ must be taken high (V_{IH} = 2.2V) and held for a minimum time period t_{PPD} and maintained at V_{IH} for the entire standby period. After power is returned to V_{CC} min or above, $\overline{CE}$ must be held high for a minimum of t_{RC} in order that the device may operate properly. See power down waveforms herein. Any active cycle in progress prior to power down must be completed so that t_{CE} min is not violated.

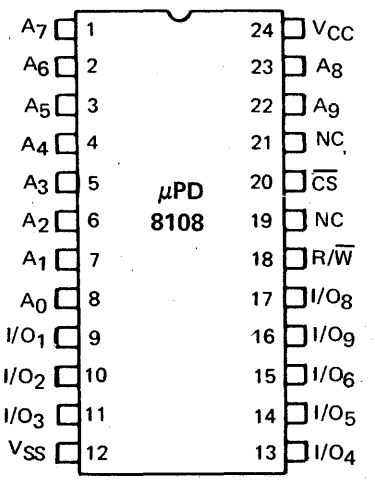
NEC
μPD8108
PRELIMINARY

8K BIT STATIC RAM



DESCRIPTION

The NEC μPD8108 is a very high speed 8192 bit static RAM. Organized as 1K x 8, it features a 22 pin dual-in-line package, full TTL compatibility, and a single +5V supply.

FEATURES

- 1024 x 8-Bit Organization
- Very Fast Access Time: 85/100/150/200 ns
- Single +5V Power Supply
- N-Channel Silicon Gate E/D Process
- 6-Device Static Cell
- Three State Common I/O
- Compatible with 8308 and Equivalent Devices
- Available in a 24 Pin Dual-in-Line Package

PIN CONFIGURATION

NC: No Connection

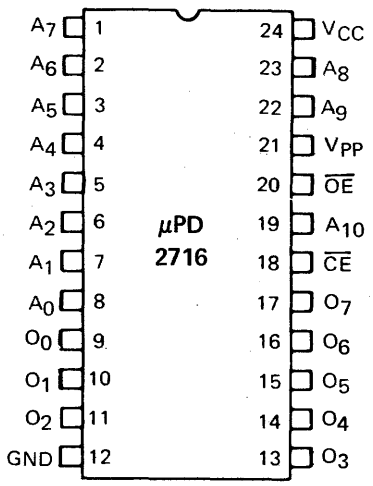
NEC
μPD2716
PRELIMINARY

16K ULTRAVIOLET ERASABLE PROM

DESCRIPTION



The μPD2716 is a 16,384-bit Ultraviolet Erasable and Electrically Programmable Read Only Memory. Organized as 2048 words x 8 bits, it operates from a single +5 volt power supply, making it ideal for microprocessor applications. It is pin-for-pin compatible with the μPD2316E, allowing economical changeover to a masked ROM for production quantities.

The μPD2716 features fast, simple, one pulse programming, controlled by TTL level signals. Total programming time for all 16,384 bits is only 100 seconds.

FEATURES

- Access Time — 450 ns Max
- 2048 Words x 8 Bits Organization
- Single +5V Supply
- Pin Compatible with μPD2316E Masked ROM
- Fast Programming
- TTL Level Controls for Reading and Programming
- Available in a 24 Pin Ceramic Package

ERASURE OPERATION

The recommended erasure procedure is to illuminate the window with a ultraviolet lamp which has a wavelength of 2537 angstroms (Å). The distance should be one inch from the window to the lamp. Erasure time will be from 19 to 45 minutes depending on the type of ultraviolet lamp. The amount of time required can be expressed as the total amount of ultraviolet energy incident to the window, expressed in watt-seconds per square centimeter. The μPD2716 requires an integrated dosage (ultraviolet intensity x exposure time) of 15 watt-seconds/cm^2. This erase energy includes sufficient guard-band to ensure complete erasure of all bits.

Timing Measurement Reference Level:
Inputs: 1V and 2V
Outputs: 0.8V and 2V

TIMING WAVEFORMS ①

Notes: ① $\overline{OE}$ may be delayed up to $t_{ACC} - t_{OE}$ after the falling edge of $\overline{CE}$ without impact on t_{ACC}.

② t_{DF} is specified from $\overline{OE}$ or $\overline{CE}$, whichever occurs first.

©IC MASTER 1979

PROGRAMMING OPERATION

Initially, and after each erasure, all bits of the μPD2716 are in the "1" state. Information is introduced by selectively programming "0" into the desired bit locations. A programmed "0" can only be changed to a "1" by UV erasure.

The μPD2716 is programmed by applying a 50 ms, TTL programming pulse to the $\overline{CE}$/PGM pin with the $\overline{CE}$ input high and the Vpp supply at 25V ± 1V. Any location may be programmed at any time – either individually, sequentially, or randomly. The programming time for a single bit is only 50 ms and for all bits is approximately 100 seconds for the μPD2716.

CAUTION: The V_{CC} and Vpp supplied must be sequenced on and off such that V_{CC} is applied simultaneously or before Vpp and removed simultaneously or after Vpp to prevent damage to the μPD2716. The maximum allowable voltage during programming which may be applied to the Vpp with respect to ground is +26V. Care must be taken when switching the Vpp supply to prevent overshoot exceeding the 26V maximum specification. For convenience in programming, the μPD2716 may be verified with the Vpp supply at 25V ± 1V. During normal read operation, however, Vpp must be at V_{CC}.

DC CHARACTERISTICS ①

T_a = 25°C ± 5°C; V_{CC} = 5V ± 5% ②; Vpp = 25V ± 1V ② ③

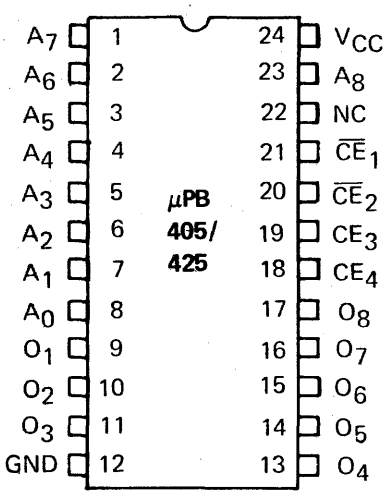
4096-BIT BIPOLAR TTL PROGRAMMABLE READ ONLY MEMORY



DESCRIPTION

The μPB405 and μPB425 are high speed, electrically programmable, fully decoded 4096-bit TTL read only memories. On-chip address decoding, four chip enable inputs and open-collector outputs allow easy expansion of memory capacity. The μPB405 and μPB425 are fabricated with logic level zero (low); logic level one (high) can be electrically programmed into the selected bit locations. The same address inputs are used for both programming and reading.

FEATURES

- 512 Words X 8 Bits Organization (Fully Decoded)
- TTL Interface
- Fast Read Access Time: 70 ns max. (μPB425)
- Medium Power Consumption: 600 mW TYP.
- Four Chip Enable Inputs for Memory Expansion
- Open-Collector Outputs (μPB405)/Three-State Outputs (μPB425)
- Ceramic 24-Lead Dual In-Line Package
- Fast Programming Time: 200 μs/bit TYP.
- Compatibility with: Intersil's IM5605/5625 (both in programming and as a ROM), Harris' HPROM HM-7640/7641 and Equivalent Devices (as a ROM).
- A.I.M. (Avalanche Induced Migration) Technology

PIN CONFIGURATION

NC: No Connection

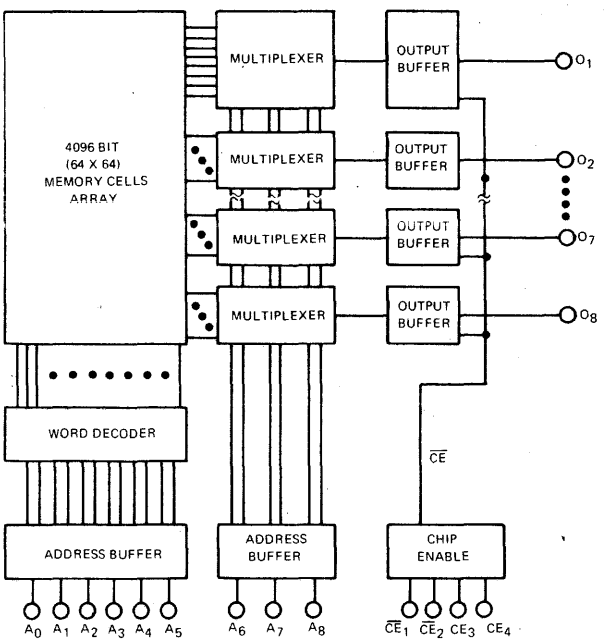
©IC MASTER 1979

OPERATION

Chip Enable logic is defined by:

$\overline{CE}_1$	$\overline{CE}_2$	CE_3	CE_4	CE'
0	0	1	1	0
All other combinations				1

Where: CE' = 0 denotes chip selected
CE' = 1 denotes chip deselected



Programming

A logic one can be permanently programmed into a selected bit location in accordance with the programming procedures specified. First, the desired word is selected by the eight TTL address inputs. The four Chip Enable inputs must be set so that CE' is a logical one. Secondly, a train of high current programming pulses is applied to the desired output. After the sensed voltage indicates that the selected bit is in the logic one state, an additional pulse train is applied, and programming is complete.

Reading

To read the memory, the four Chip Enable inputs must be set so that CE' is a logical zero. The outputs then correspond to the data programmed in the selected words. When the four Chip Enable inputs are set so that CE' becomes a logical one, all the outputs will be high (floating).

PROGRAMMING SPECIFICATION

It is imperative that this specification be rigorously observed in order to correctly program the μPB405 and μPB425. NEC will not accept responsibility for any device found to be defective if it were not programmed according to this specification.

A typical programming operation is performed by first sensing, then programming, then sensing again to see if the word to be programmed has reached the desired state.

Sensing is accomplished by forcing a 20 mA current into the selected location via the output. The μPB405 and μPB425 are disabled in accordance with the truth table on page 2. The sense measurement is to ensure that the voltage required to force this 20 mA current is less than the reference voltage. If this condition is satisfied, then that bit location is in the logic "1" (high) state.

Programming is accomplished by forcing a 200 mA current into the selected bit via the output. This current pulse is applied for 7.5 μs and then the location is sensed before a second programming current pulse is applied. This process is continued until that location is altered to the "1" state. A bit is judged to be programmed when two successive sense readings 10 μs apart with no intervening programming pulse, pass the limit. When this condition has been met, four additional pulses are applied and the pulse train, then the sense current is terminated.

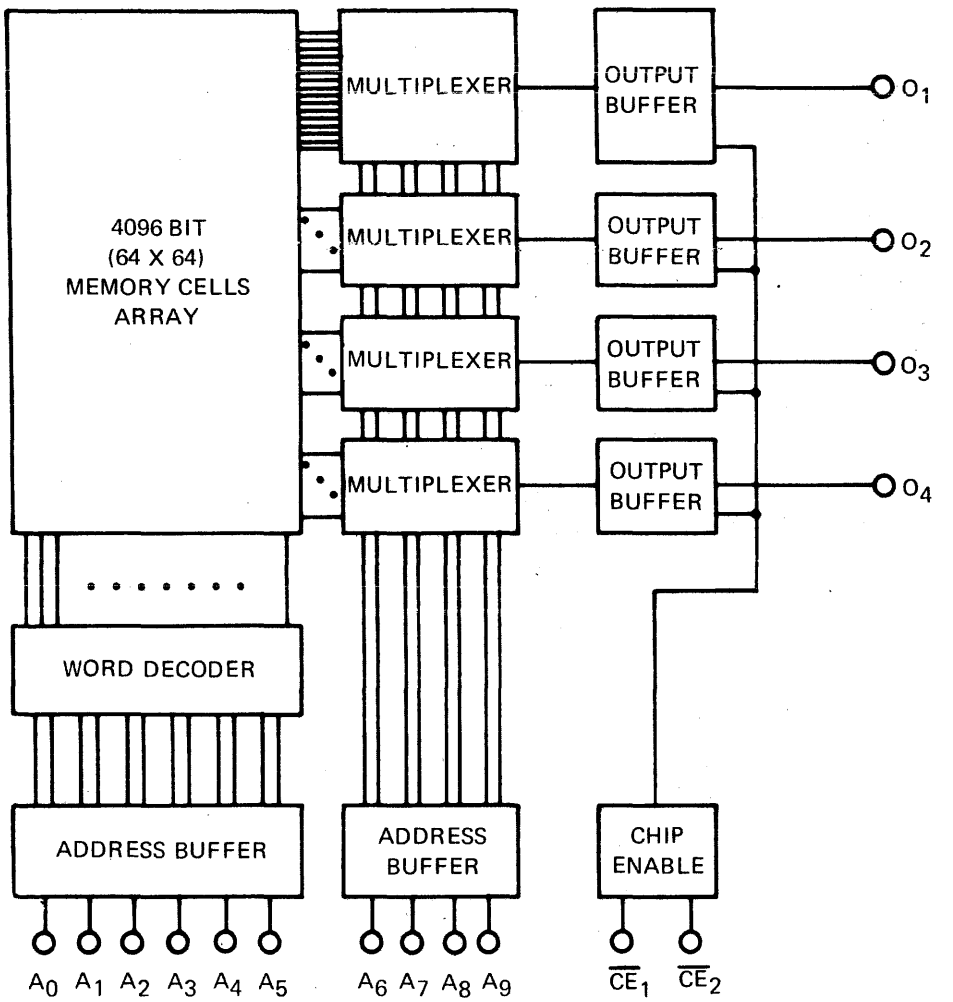
OPERATION



Programming

A logic one can be permanently programmed into a selected bit location by using special equipment (programmer). First, the desired word is selected by the ten address inputs in TTL levels. Either or both of the two chip enable inputs must be at a logic one (high). Secondly, a train of high current programming pulses is applied to the desired output. After the sensed voltage indicates that the selected bit is in the logic one state, an additional pulse train is applied, then is stopped.

Reading

To read the memory, both of the two chip enable inputs should be held at logic zero (low). The outputs then correspond to the data programmed in the selected words. When either or both of the two chip enable inputs are at logic one (high), all the outputs will be high (floating).

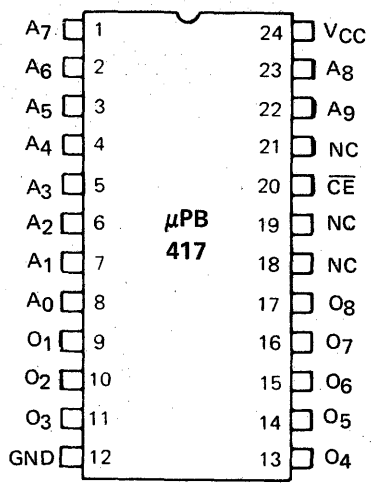
8192 BIT BIPOLAR TTL PROGRAMMABLE READ ONLY MEMORY



DESCRIPTION

The μPB417 is a high speed, electrically programmable, fully decoded 8192-bit TTL read only memory. On-chip address decoding, two chip enable input and three-state outputs allow easy expansion of memory capacity. The μPB417 is fabricated with logic level zero (low); logic level one (high) can be electrically programmed into the selected bit locations. The same address inputs are used for both programming and reading.

FEATURES

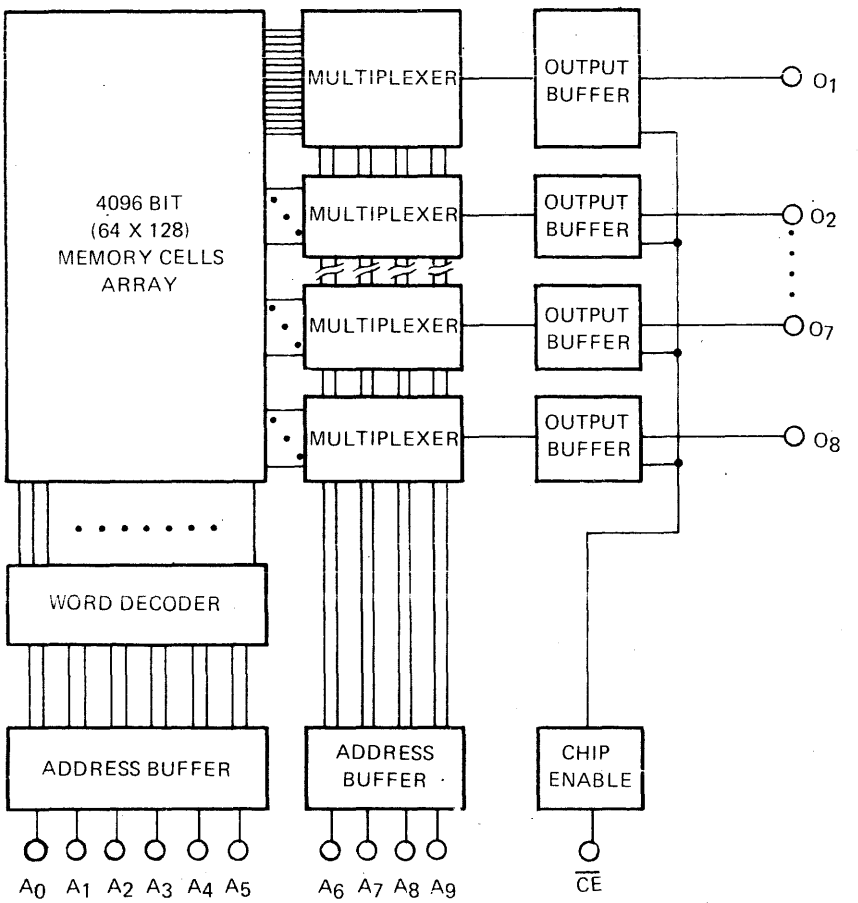
- 1024 Words x 8 Bits Organization (Fully Decoded)
- TTL Interface
- Fast Read Access Time: 200 ns Max.
- Power Dissipation: 500 mW Typ.
- Two Chip Enable Inputs for Memory Expansion
- Three-State Outputs
- Fast Programming Time: 200 μs/bit Typ.
- Direct Replacement for 2708 and Equivalent Devices (as a ROM)
- Available in Plastic and Ceramic 24 Pin Packages

PIN CONFIGURATION

NC: No Connection

©IC MASTER 1979

OPERATION



Programming

A logic one can be permanently programmed into a selected bit location by using special equipment (programmer). First the Chip Enable CE must be a logical one in order to disable the outputs. Second, the desired word is selected by the ten address inputs in TTL levels. Third, a train of high current programming pulses is applied to the desired output. After the sensed voltage indicates that the selected bit is in the logic one state, an additional pulse train is applied, then is stopped.

Reading

To read the memory, the Chip Enable input must be a logical zero. The outputs then correspond to the data programmed in the selected words. When the Chip Enable input is a logical one, all the outputs will be disabled (floating).

Notes: ① Output Load: See Figure 1.
② Input Waveform: 0.0V for low level and 3.0V for high level, less than 10 ns for both rise and fall times.
③ Measurement References: 1.5V for both inputs and outputs.
④ C_L in Figure 1 includes jig and probe stray capacitances.

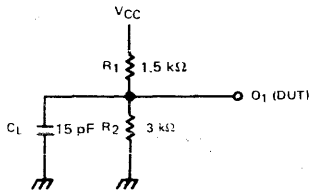

Figure 1

PROGRAMMING SPECIFICATION

It is imperative that this specification be rigorously observed in order to correctly program the μPB417. NEC will not accept responsibility for any device found to be defective if it were not programmed according to this specification.

CHARACTERISTIC	LIMIT	UNIT	NOTES
Ambient Temperature	25 ± 5	°C	
Programming Pulse			
Amplitude	200 ± 5%	mA	
Clamp Voltage	28 + 0% − 2%	V	
Ramp Rate (both in Rise and in Fall)	70 Max.	V/μs	
Pulse Width	7.5 ± 5%	μs	15V point/ 150Ω load.
Duty Cycle	70% Min.		
Sense Current			
Amplitude	20 ± 0.5	mA	
Clamp Voltage	28 + 0% − 2%	V	
Ramp Rate	70 Max.	V/μs	15V point/ 150Ω load.
Sense Current Interruption before and after address change	10 Min.	μs	
Programming V_{CC}	5.0 + 5% − 0%	V	
Maximum Sensed Voltage ① for programmed "1"	7.0 ± 0.1	V	
Delay from trailing edge of programming pulse before sensing output voltage	0.7 Min.	μs	

Note: ① A bit is judged to be programmed when two successive sense readings 10 μs apart with no intervening programming pulse, pass the limit. When this condition has been met, four additional pulses are applied and the pulse train, then the sense current is terminated.

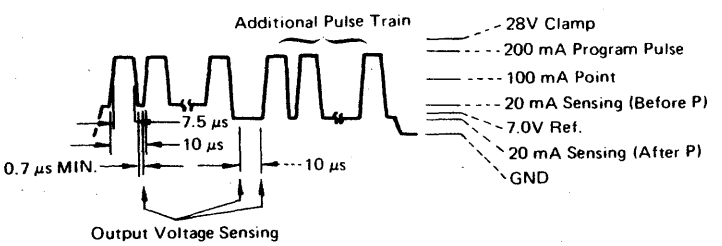

Figure 2 — Typical Output Voltage Waveform

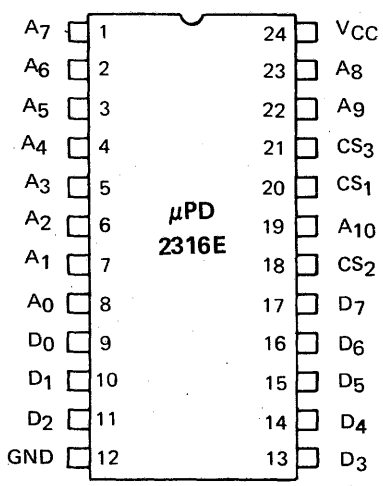
FULLY DECODED 16,384 BIT MASK PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION



The NEC μPD2316E is a high speed 16,384 bit mask programmable Read Only Memory organized as 2048 words by 8 bits. The μPD2316E is fabricated with N-channel MOS technology.

The inputs and outputs are fully TTL compatible. The device operates with a single +5V power supply. The three chip select inputs are programmable. Any combination of active high or low level chip select inputs can be defined and desired chip select code is fixed during the masking process.

FEATURES

- Access Time 450 ns Max
- 2048 Words x 8 Bits Organization
- Single +5V ±10% Power Supply Voltage
- Directly TTL Compatible – All Inputs and Outputs
- Three Programmable Chip Select Inputs for Easy Memory Expansion
- Three-State Output – OR-Tie Capability
- On-Chip Address Fully Decoded
- All Inputs Protected Against Static Charge
- Direct Replacement for 2316E
- Available in 24-pin plastic or ceramic packages

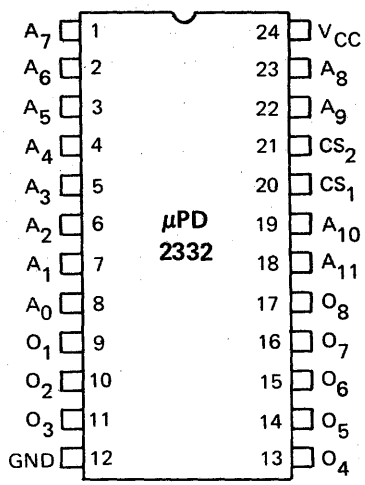
FULLY DECODED 32,768 BIT MASK PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION



The NEC μPD2332 is a Fully Decoded 32,768 Bit Mask Programmable Read-Only Memory organized as 4,096 Words by 8 Bits. The μPD2332 has two chip select inputs and the combination of "High"/"Low" levels of these inputs is mask-programmable.

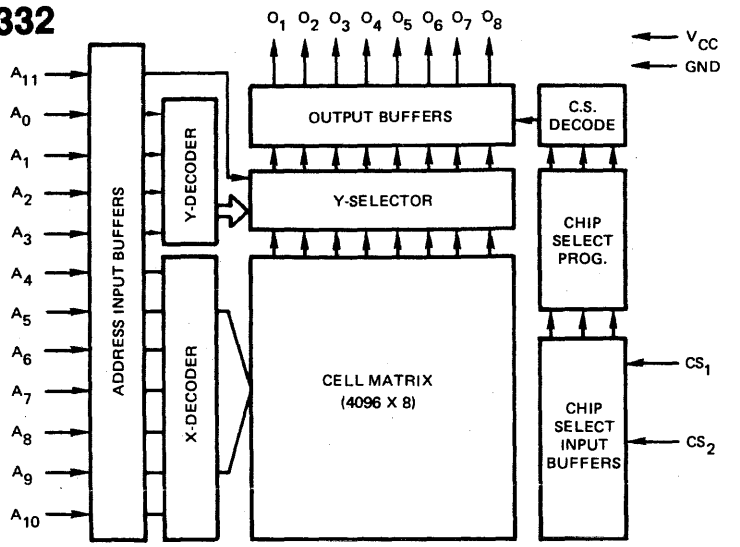
The μPD2332 is fabricated with sophisticated N-channel MOS technology and features high speed and TTL compatibility for simple interface with bipolar circuits.

FEATURES

- 4096 Words x 8 Bits Organization
- Directly TTL Compatible – All Inputs and Outputs
- Fully Static (No Clock or Refresh Required)
- Single +5V Power Supply
- High Speed – Access Time 450 ns Max.
- Three-State Output – OR-Tie Capability
- Two Programmable Chip Select Inputs for Easy Memory Expansion
- N-Channel MOS Technology
- Pin Compatible with TI TMS4732
- 24 Pin Plastic or Ceramic Dual-in-Line Package

PIN CONFIGURATION

PIN NAMES



$A_0 - A_{11}$	Address Inputs
$O_1 - O_8$	Data Outputs
$CS_1 - CS_2$	Programmable Chip Select Inputs

When ordering the μPD2332, specify a chip select combination of CS_1 and CS_2 from the following.

CS_2	CS_1
0	0
0	1
1	0
1	1

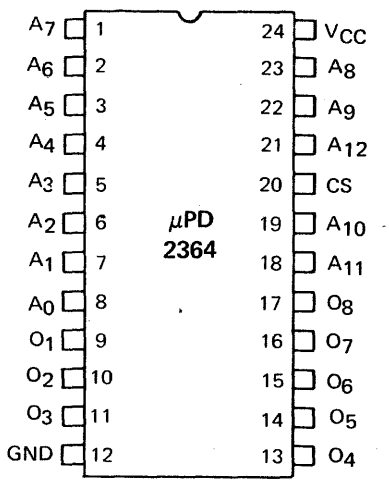
FULLY DECODED 65,536 BIT MASK PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION



The NEC μPD2364 is a high speed 65,536 bit mask programmable Read Only Memory organized as 8,192 words by 8 bits. The μPD2364 is fabricated with N-channel MOS technology.

The inputs and outputs are fully TTL compatible. This device operates with a single +5V power supply. The chip select input is programmable. Any of active high or low level chip select input can be defined and desired chip select code is fixed during the masking process.

FEATURES

- 8,192 Words x 8 Bits Organization
- Directly TTL Compatible — All Inputs and Outputs
- Single +5V Power Supply
- High Speed — Access Time 450 ns Max.
- Three-State Output — OR-Tie Capability
- One Programmable Chip Select Input for Easy Memory Expansion
- On-Chip Address Fully Decoded
- All Inputs Protected Against Static Charge
- Pin Compatible with MK36000
- Available in 24 Pin Ceramic Dual-in-Line Package

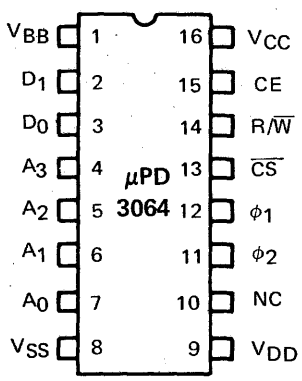
65,536 BIT CCD MEMORY

DESCRIPTION

The μPD3064 is a high speed, dynamic, 65,536 bit Charge Coupled Device (CCD) memory. It is organized as 65,536 x 1 in 16 addressable blocks of 4096 bits each. Operating clock frequency is from 1 MHz to 5 MHz.



With the exception of the two clocks and chip enable, all inputs are TTL compatible. The use of only two clocks simplifies system design.

The μPD3064 is packaged in a standard, 16 pin dual-in-line with 400-mil centers.

FEATURES

- High Speed: Latency Time at 5 MHz (max) – 820 μs
  Read or Write Cycle (min) – 200 ns
  Read, Modify, Write Cycle (min) – 300 ns
- Fully TTL Compatible Except ϕ_1, ϕ_2, and CE
- Low Power Operation: 260 mW Operating (Typical at 5 MHz)
  25 mW Recirculating (Typical at 1 MHz)
  <1 mW Standby (Typical)
- Two-Phase CCD Clocks

Field-Programmable Read-Only Memories

29000 Series

DESCRIPTION

Raytheon's 29000 Series of Field-Programmable Read-Only Memories includes most of the popular PROM configurations in both standard and power-switched versions. The power-switched devices (SPROMs) were originated by Raytheon to reduce overall power dissipation in large PROM arrays. This technique takes advantage of the non-volatile nature of PROMs by removing power when a particular device is not being used in the system. Unlike previous power-switching schemes, which employed external transistors and resistors, the SPROM includes all power-switching circuitry on the same chip as the memory. Moreover, the power-switch is activated by the same Chip Select (CS) input that is used to address a standard PROM; thus, in most cases, SPROMs can be directly substituted for standard devices without system redesign.

All Raytheon 29000 Series PROMs and SPROMs are manufactured with nichrome fuses and Low-Power Schottky technology. The devices are shipped with all bits in the HIGH (logical ONE) state. To achieve a LOW state in a given bit position, the nichrome link is fused open by passing a short, high-current pulse through the link. All 29000 Series devices are programmed using the same programming technique. (See page 3.)

FEATURES

- Low-Power Schottky technology
- Highly reliable nichrome fuses
- Three-state and open-collector versions
- PROM and SPROM versions of most configurations
- Typical SPROM "OFF" power is 25% of standard power
- SPROMs feature guaranteed access times and full V_{CC} tolerance under power-switched conditions
- All devices use same programming techniques (generic)
- All devices available in both commercial (0 to 75°C) and military (-55 to +125°C) versions
- All devices are industry standard pin-out

ORDERING INFORMATION

Configuration (Words x Bits)	Package (No. of Pins)	Output	Part Numbers			
			PROMs		SPROMs

MAXIMUM RATINGS (Above which the useful life may be impaired)

Storage temperature . . . . . -65 to +150°C
Temperature (ambient) under bias . . . -55 to +125°C
Supply voltage to ground potential (continuous) . . . . . -0.5 to +7V
DC voltage applied to outputs (except during programming) . . -0.5V to +V_{CC} max
DC input voltage (address inputs) . . . -0.5 to +5.5V
DC voltage applied to outputs during programming 26V
Output current into outputs during programming . . . . . 125 mA
DC input voltage (chip select input - pin) . -0.5 to +33V
DC input current . . . . . -30 to +5 mA

OPERATING RANGE

29000XC	T_A = 0 to +75°C	V_{CC} = 5.0V ±5%	Commercial
29000XM	T_A = -55 to +125°C	V_{CC} = 5.0V ±10%	Military

COMMON ELECTRICAL CHARACTERISTICS OVER OPERATING RANGE (unless otherwise noted)

Parameter	Description	Test Conditions		Min.	Typ.	Max.	Units
V_{OH} (tri-state only)	Output HIGH voltage	V_{CC} = MIN, I_{OH} = 2.0 mA V_{IN} = V_{IH} or V_{IL}		2.4			Volts
V_{OL}	Output LOW voltage	V_{CC} = MIN V_{IN} = V_{IH} or V_{IL}	I_{OL} = 8 mA			0.4	Volts
			I_{OL} = 16 mA			0.5	
V_{IH}	Input HIGH level	Guaranteed input logical HIGH voltage for all inputs		2.0			Volts
V_{IL}	Input LOW level	Guaranteed input logical LOW voltage for all inputs				0.8	Volts
I_{IL}	Input LOW current	V_{CC} = MAX, V_{IN} = 0.4V			-60	-250	μA
I_I	Input HIGH current	V_{CC} = MAX, V_{IN} = 2.7V				10	μA
I_I	Input HIGH current	V_{CC} = MAX, V_{IN} = 5.5V				1.0	mA
I_I (program pin only)	Input HIGH current	V_{CC} = MAX, V_{IN} = 4.5V				1.0	mA
I_{SC} (tri-state only)	Output short circuit current	V_{CC} = MAX, V_{OUT} = 0.0V		-12	-35	-85	mA
V_I	Input clamp voltage	V_{CC} = MIN, I_{IN} = 18 mA				-1.5	V
I_{CEX}	Output leakage current	V_{CC} = MAX V_{CS} = 2.4V	V_O = 4.5V			100	μA
			V_O = 2.4V			40	
			V_O = 0.4V			-40	

Note: 1. Typical limits are at V_{CC} = 5.0V and T_A = 25° C
2. Not more than one output should be shorted at a time. Duration of the short circuit should not be more than one second.

AC TEST CONDITIONS

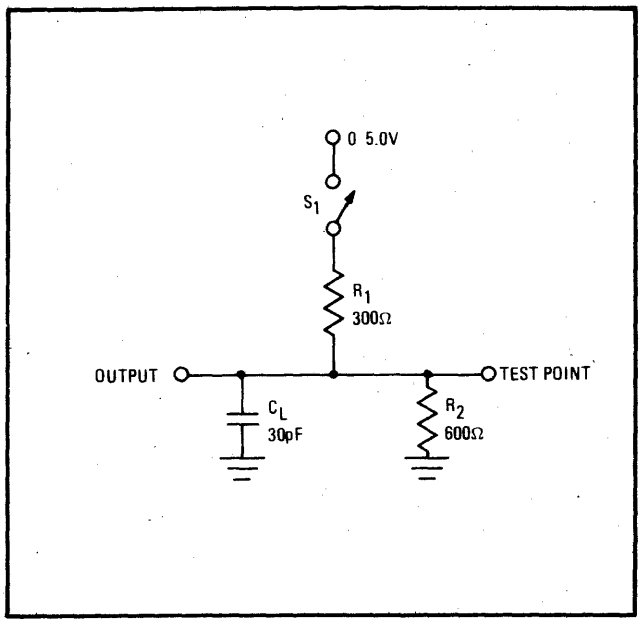

Figure 1. AC Test Circuit

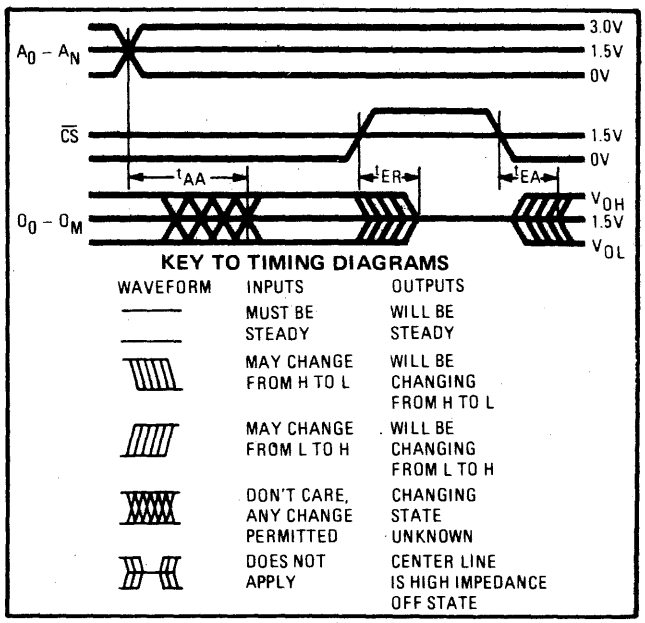

Figure 2. Switching Waveforms

PROGRAMMING INSTRUCTIONS

GENERAL

The device is manufactured with all outputs high in all storage locations. To make an output low at a particular word, a nichrome fusible link must be opened. This procedure is called programming.

PROGRAMMING DESCRIPTION

To select a particular link for programming, the word address is presented with TTL levels on A_0 through A_N, a V_{CC} of 5.50V is applied or left applied, and the program pin and the output to be programmed is taken to an elevated voltage to supply the required current to the fuse. The outputs must be programmed one at a time, since internal decoding circuitry is capable of sinking only one unit of programming current.

OTHER CHIP SELECT INPUTS

On some devices, additional Chip Select Inputs are present. These may be high, low or open during programming. When checking that an output is programmed (which is called verification) these inputs must be "on" to activate the device. Since they must be "on" during verification and the state is irrelevant during programming, the simplest procedure is to activate them during the entire procedure.

TIMING

The programming procedure involves the use of the program pin (a chip select) and the output pin. In order to guarantee that the output transistor is off before increasing the voltage on the output pin, the program pin's voltage pulse must come before the output pin's programming pulse and leave after the output pin's programming pulse. 100 ns delay is adequate. The programming pulse applied to the output pin and program pin must have a 50 to 70 microsecond rise time. See Figure 3.

It is recommended that only one programming pulse be applied for each bit to be programmed.

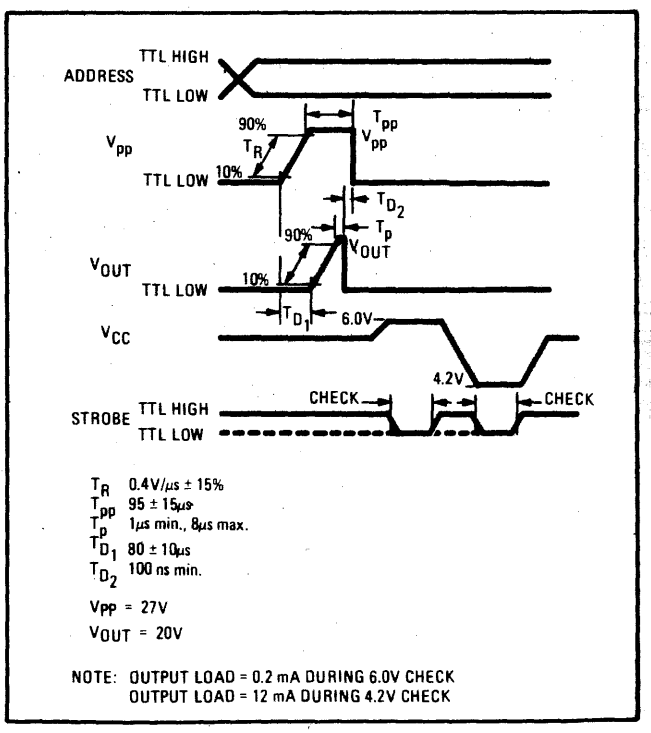

Figure 3. Programming Timing

©IC MASTER 1979

VERIFICATION

After programming a device, it can be checked for a low output by turning all chip selects on. To guarantee operation at minimum and maximum Vcc, current and temperature, the device must sink 12 mA at 4.20V Vcc and 20 mA at 6.0V Vcc at room temperature.

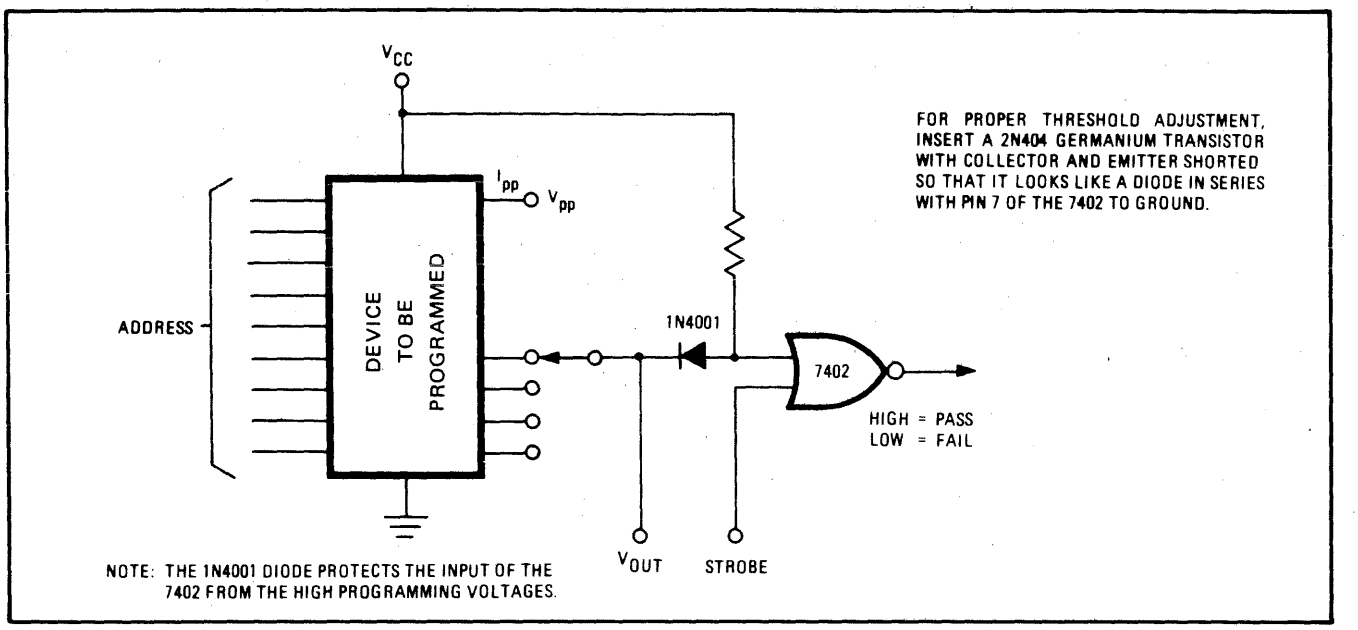

Figure 4. Suggested Implementation of the Verification Circuitry

BOARD PROGRAMMING

Units may be programmed at the board level by bringing the program pin of each package to the card connector. To program a particular package "A", the program pin of package A and one output of package A, which may or may not be "OR" tied to other packages, are taken to the required programming voltage. An alternate procedure is to tie the enable and outputs together as required by the system function and only apply V_{CC} to the device to be programmed. The number of units soldered on a board should be consistent with expected programming yields to avoid rework.

UNPROGRAMMABLE UNITS

Visual inspection at 200X prior to encapsulation, test fuses and decoding circuitry tests are used to guarantee a high programming yield of the device in the field. However, because of random defects, it is impossible to guarantee that a link will open without actually programming it. UNITS RETURNED TO RAYTHEON AS UNPROGRAMMABLE MUST BE ACCOMPANIED BY A COMPLETE DEVICE TRUTH TABLE WITH THE LOCATION WHICH COULD NOT BE PROGRAMMED, OR WHICH FALSELY PROGRAMMED, CLEARLY INDICATED.

RAYTHEON

PROGRAMMING PARAMETERS — Do not test these limits or you may program the device

Parameter	Description	Test Conditions	Min.	Typ.	Max.	Units
I_{pp}	Current program pin during programming, before and after fuse has blown	V_{CC} = 5.50V V_{out} = 5.0V to 25V V_{pp} = 4.50V		0		mA
		V_{pp} = 27V		77		mA
I_{out}	Current into output during programming before the fuse has programmed	V_{pp} = 27V, V_{CC} = 5.50V V_{out} = 9.0V		0.1		mA
		V_{out} = 20V		16		mA
I_{out}	Current into output during programming after the fuse has programmed	V_{pp} = 27V V_{out} = 20V V_{CC} = 5.50V		0.1		mA
T_R	Rise time of program pulse applied to the data out or program pin		0.34	0.4	0.46	V/μs
V_{CCP}	V_{CC} required during programming		5.40	5.50	5.60	V
I_{OLV_1}	Output current required during verification	Both chip enables low T_A = 25°C, V_{CC} = 4.2V	11	12	13	mA
I_{OLV_2}	Output current required during verification	Both chip enables low	0.19	0.2	0.21	mA
MDC	Maximum duty cycle during automatic programming of program pin and output pin	$\frac{T_p}{T_C}$			25	%
V_{pp}	Required programming voltage on program pin		27	27	33	V
V_{out}	Required programming voltage on output pin		20	20	26	V
I_L	Required current limit of the power supply feeding the program pin and the output during programming	V_{pp} = 33V V_{out} = 26V V_{CC} = 5.50V	150			mA
T_{pp}	Required coincidence among the program pin, output, address and V_{CC} for programming		80	95	110	μs
T_{D_1}	Required time delay between disabling the memory output and application of the output programming pulse	Measure at 10% levels	70	80	90	μs
T_{D_2}	Required time delay between removal of programming pulse and enabling the memory output	Measure at 10% levels	100			ns

©IC MASTER 1979

TRUTH TABLES

Raytheon can program devices at our facility from Raytheon truth table forms (see page 8). For customers desiring to make their own forms, an example is shown below:

EXAMPLE FOR X8 DEVICES:

WORD NUMBER	PIN	OUTPUTS 14 O_8	13 O_7	12 O_6	11 O_5	9 O_4	8 O_3	7 O_2	6 O_1
0		H	H	H	L	H	L	L	L
1		L	H	L	H	H	H	H	L
.		.	.	.	.	.	.	.	.
.		.	.	.	.	.	.	.	.
Last		L	H	H	H	H	H	H	H

EXAMPLE FOR X4 DEVICES:

WORD NUMBER	PIN	OUTPUTS 9 O_4	10 O_3	11 O_2	12 O_1
0		H	H	H	L
1		L	H	L	H
.		.	.	.	.
.		.	.	.	.
Last		L	H	H	H

Note: A high voltage on the data out lines is signified by an "H". A low voltage on the data out lines is signified by an "L". The word number assumes positive logic on the address pins, so for example, word 511 = HHHHHHHHH.

PAPER TAPE FORMAT

Truth tables can also be sent to Raytheon in an ASCII tape format. Information can be sent to us by air mail or TWX 910-379-6481. The tape reading equipment at Raytheon only recognizes ASCII characters S, B, P, N, F, and E and interprets them as:

S	Start
B	Begin a word
P	High data
N	Low data
F	Finish a word
E	End of tape

All other characters such as carriage returns, line feeds, etc. are ignored so that comments and spaces may be sent in the data field to improve readability. Comments, however, should not use the characters S, B, P, N, F, and E. Word addresses must begin with zero and count sequentially to the highest address.

In order to assist the machine operator in determining where the heading information stops and the data field begins, 25 bell characters or rubout characters should precede the start of the truth table. Any type of 8 level tape (paper, mylar, fanfold, etc.) is acceptable. Channel 1 is the most significant bit and channel 8 (parity) is ignored. Sprocket holes are located between channels 3 and 4. Note that the order of the outputs between characters B and F is:

$$O_8, O_7, O_6, O_5, O_4, O_3, O_2, O_1$$

not

$$O_1, O_2, O_3, O_4, O_5, O_6, O_7, O_8$$

A typical list of characters and their machine interpretations are shown on page 7.

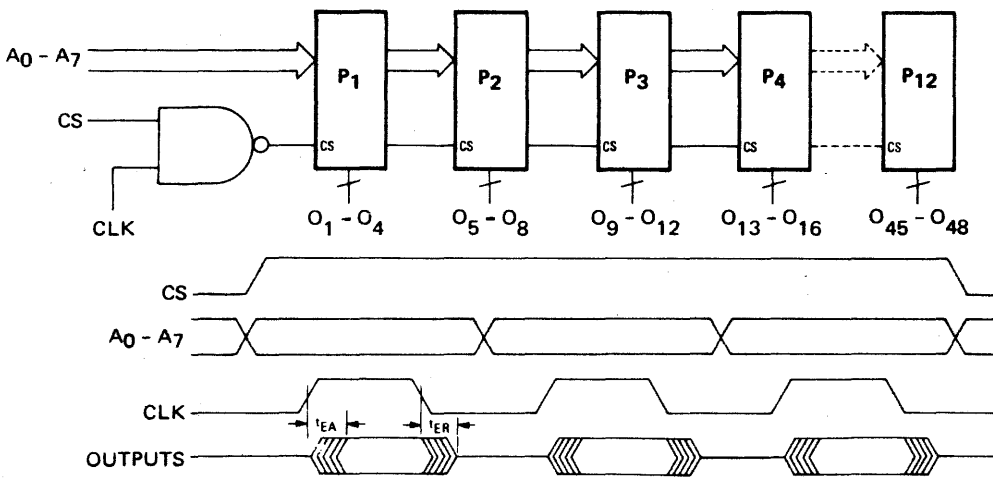
SPROM Applications

1024 x 16 BIT PROM ARRAY EXAMPLE USING 256 x 4 SPROMs

TYPICAL POWER DISSIPATION

Without Power Switching:

16 devices X 450 mW/device = 7.2 watts



With Power Switching (29662):

4 devices X 450 mW/device = 1.8 watts

12 devices X 100 mW/device = 1.2 watts

Total Power = 3.0 watts

256 x 48 BIT CLOCKED PROM APPLICATIONS USING 256 x 4 SPROMs

TYPICAL POWER DISSIPATION

Without Power Switching:

12 devices X 450 mW/device = 5.4 watts

With Power Switching (29662 and 50% duty cycle clock):

(0.5 X 12 devices X 450 mW/device) + (0.5 X 12 devices X 100 mW/device) = 3.3 watts

With Power Switching (29662 and 20% duty cycle clock):

(0.2 X 12 devices X 450 mW/device) + (0.8 X 12 devices X 100 mW/device) = 2.04 watts

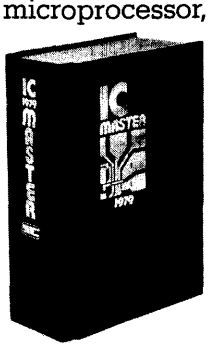
"I need to know if this device exists, and if there are any alternate sources. Where do I start?"

- Memory IC
- RAM
- Static
- 1024x1
- CMOS
- 250 Nanoseconds
- 5 Volts

If you're spending hours to solve a problem similar to the one above, you're behind the times...



It only takes a few seconds with "THE MASTER."

Clear your desk for action with the newly revised 1979 IC Master. Its all-under-one-cover features include: Over 40,000 standard products from more than 87 different companies . . . five different selection guides (memory, microprocessor, interface, linear and digital.) . . . alternate source directory for pin- for- pin, function- for- function replacements . . . applications directory . . . complete military section . . . a complete part numbering guide . . . etc.

You don't have to search through stacks of catalogs. Simply look up the specs and function you need. You don't need a part number to start with.

All you need is a problem to use The Master. Does the device exist? Who makes it? Is there an alternate source? What's the part number? Is there an applications note? Who is my closest distributor—etc.

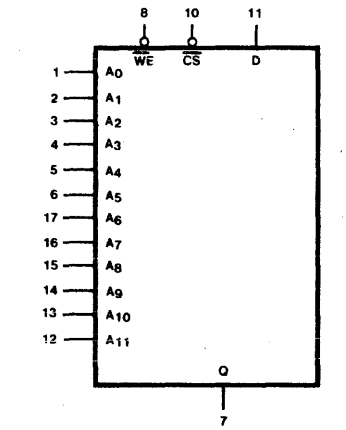
DESCRIPTION



The Signetics 2613 is a high speed, 4096 bit static random access memory. Utilizing the Signetics n-channel, si-gate Mini-MOS technology to achieve high performance and high bit density, the 4096x1 organization offers a cost effective solution for designer needs.

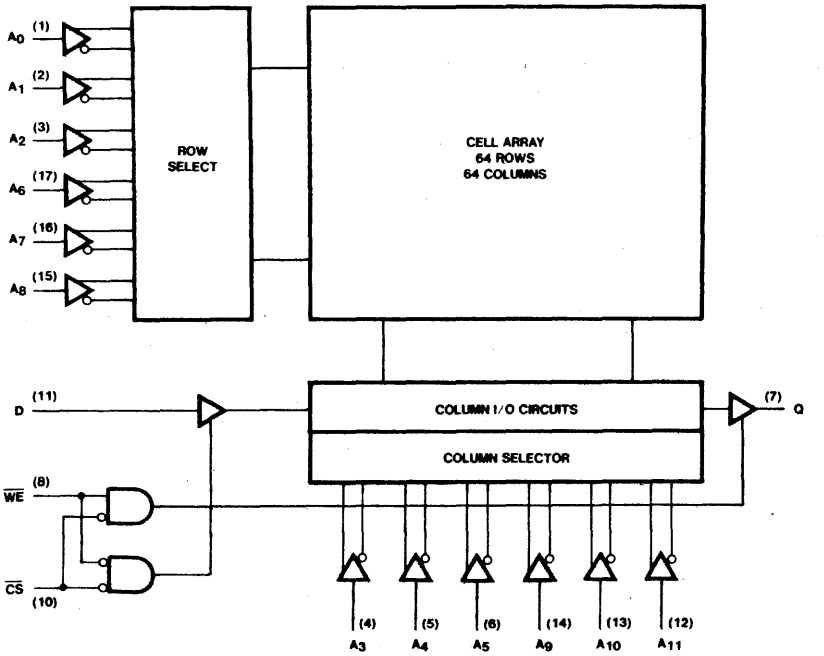
The 2613 is fully static (access time=cycle time), all input and outputs are TTL compatible, and it has a single +5V supply. It is manufactured in the industry standard pinout 18 pin package.

FEATURES

- **Typical access time 80ns**
- **Power dissipation 0.1 mW/bit typical**
- **3-state TTL compatible output**
- **All inputs TTL compatible**
- **Fully static operation**
- **Identical access & cycle times**
- **High output impedance during write**
- **Single +5V power supply**
- **Standard 18-pin DIP**

LOGIC SYMBOL

V_{CC} = Pin 18
GND = Pin 9



ORDERING CODE (See Package Section for further information)

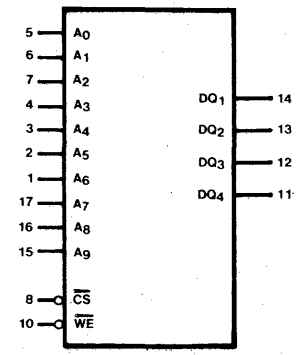
DESCRIPTION



The Signetics 2614 is a high speed, 4096 bit static random access memory. Utilizing the Signetics n-channel, si-gate Mini-MOS technology to achieve high performance and high bit density, the 1024 x 4 organization offers a cost effective solution for designer needs.

The 2614 is fully static (access time = cycle time), all input and outputs are TTL compatible, and it has a single +5V supply. It is manufactured in the industry standard pinout 18 pin package.

FEATURES

- **Typical access time of 80ns**
- **Power dissipation of 0.1mW/bit typical**
- **3-state TTL compatible output**
- **All inputs TTL compatible**
- **Fully static operation**
- **Identical access & cycle time**
- **Single +5V power supply**
- **Standard 18-pin DIP**

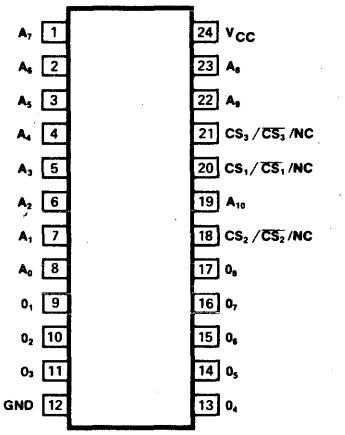
DESCRIPTION

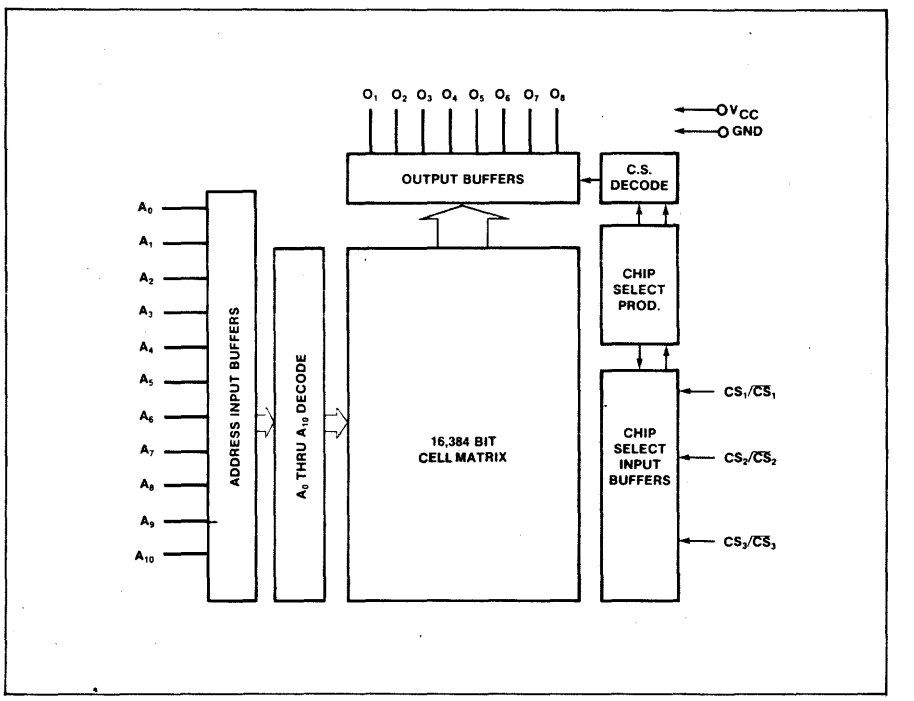
The Signetics 2616 is a 16,384-bit static MOS read-only memory organized as 2048 words by 8 bits. This ROM is designed for memory applications where high performance, large bit storage, and simple interfacing are important design objectives.

The inputs and outputs are fully TTL compatible. This device operates with a single 5V power supply. The three chip select inputs are programmable. Any combination of active high or low level chip select inputs can be defined by the designer and the desired chip select logic level is fixed during the masking process. These three programmable chip select inputs, as well as OR-tie compatibility on the outputs, facilitates easy memory expansion.



The 2616 read-only memory is fabricated with n-channel silicon gate technology. This technology provides the designer with high performance, easy-to-use MOS circuits. Only a single 5V power supply is needed and all devices are directly TTL compatible.

FEATURES



- **Single 5V power supply**
- **Guaranteed 350/450ns access time**
- **Directly TTL compatible—all inputs and outputs**
- **Three programmable chip select inputs for easy memory expansion or no connection option**
- **Three-state output—OR-tie capability**
- **Fully decoded—on chip address decode**
- **Inputs protected—all inputs have protection against static charge**

NOTES

1. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or at any other condition above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
2. Input levels that swing more negative than -0.5V will be clamped and may cause damage to the device.
3. This parameter is periodically sampled and is not 100% tested.

TIMING DIAGRAM

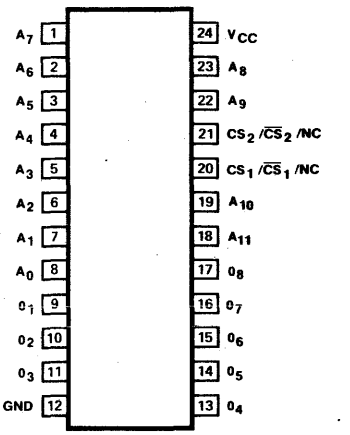
OBJECTIVE SPECIFICATION 2632-F,I,N

DESCRIPTION

This ROM is designed for memory applications where high performance, large bit storage, and simple interfacing are important design objectives.

The two chip select inputs are programmable. Any combination of active high or low level chip select inputs can be defined by the designer and the desired chip select logic level is fixed during the masking process. These two programmable chip select inputs, as well as OR-tie compatibility on the outputs, facilitates easy memory expansion.



The 2632 Read Only Memory is fabricated with n-channel silicon gate technology. This technology provides the designer with high performance, easy-to-use MOS circuits.

FEATURES

- **Guaranteed 450ns address time**
- **Completely TTL compatible**
- **Single +5V power supply**
- **3-state output—OR-tie capability**
- **Fully decoded—on chip address decode**
- **Inputs protected—all inputs have protection against static charge**

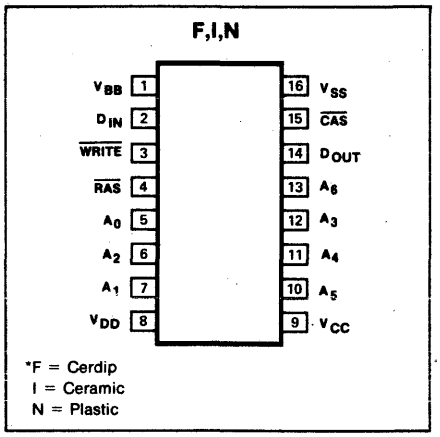
OBJECTIVE SPECIFICATION

2690-2—F,I,N • 2690-3—F,I,N • 2690-4—F,I,N

DESCRIPTION

The 2690 is fabricated with double-poly n-channel silicon gate technology for high performance and high functional density. It uses a single transistor dynamic storage cell and dynamic circuitry to achieve high speed and low power dissipation.

The unique design of the 2690 allows it to be packaged in the industry standard 16-pin in-line package, which provides the highest system bit densities and is compatible with widely available automated handling equipment.



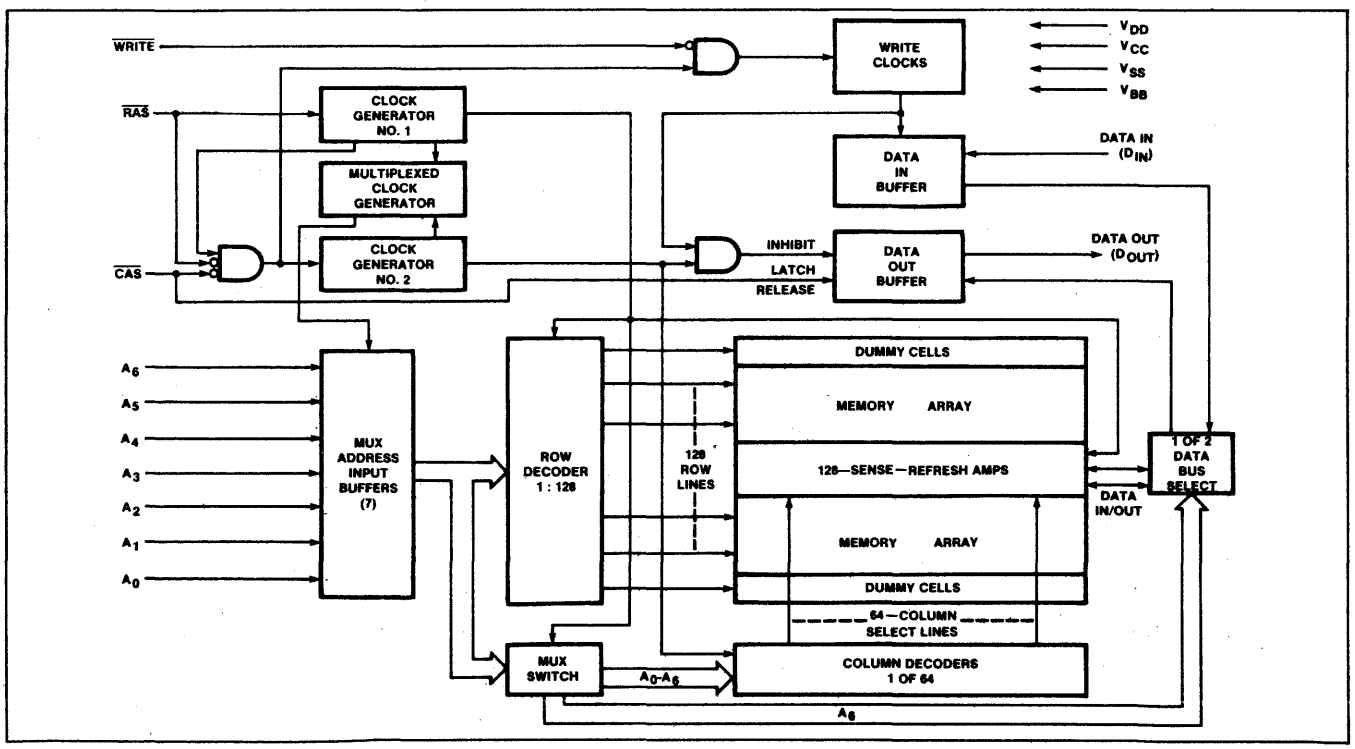
The use of the 16-pin package is made possible by multiplexing the 14 address bits (required to address one of 16,384 bits) into the 2690 on 7 address input pins. The two 7-bit address words are latched into the device by the 2 TTL clocks, Row Address Strobe ($\overline{RAS}$) and Column Address Strobe ($\overline{CAS}$). Non-critical clock timing requirements allow use of the multiplexing technique while maintaining high performance.

The memory cell requires refreshing for data retention. This is most easily accomplished by performing a $\overline{RAS}$ only cycle at each of 128 row addresses every 2ms.

FEATURES

- **Access time:**
  2690-2: 150ns
  2690-3: 200ns
  2690-4: 250ns
- **Read and write cycle time:**
  2690-2: 375ns
  2690-3: 375ns
  2690-4: 410ns
- **Low power:**
  Operating: 462mW (max)
  Standby: 20mW (max)
- **±10% power supply margins**
- **On-chip latches for address and data in**
- **Output data controlled by $\overline{CAS}$ and unlatched at end of cycle to allow 2-dimensional chip selection and extended page boundary**
- **Page mode addressing**
- **$\overline{RAS}$ only refresh**
- **Common I/O capability using "early write" operation**
- **All inputs TTL compatible**
- **3-state TTL compatible output**

PIN CONFIGURATION



*F = Cerdip
I = Ceramic
N = Plastic

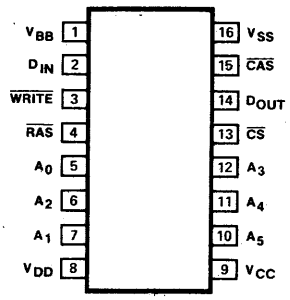
4027-2/4027-3/4027-4–F,I,N

DESCRIPTION

The 4027 is fabricated with n-channel silicon gate technology for high performance and high functional density, and uses a single transistor dynamic storage cell and dynamic circuitry to achieve high speed and low power dissipation.

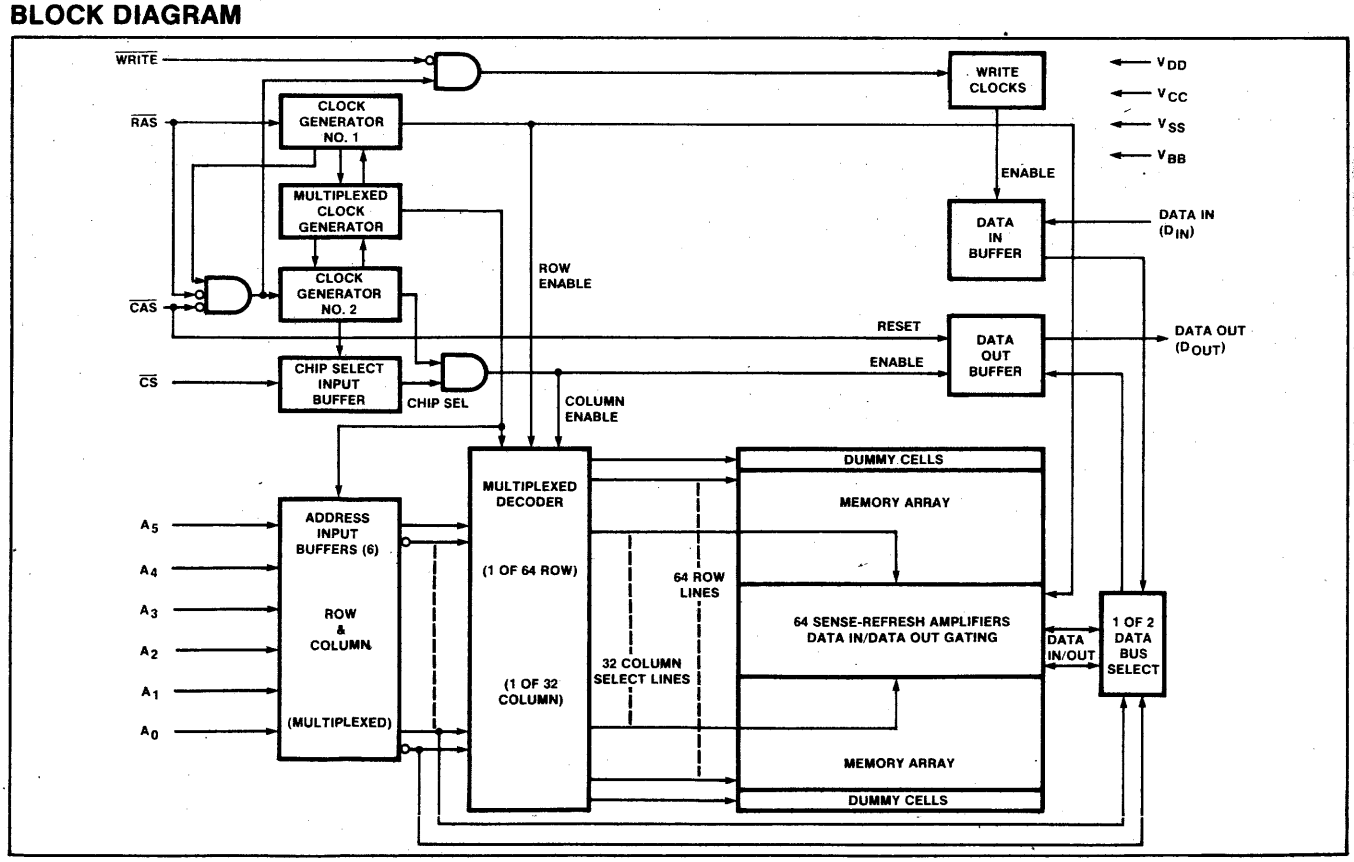
The unique design of the 4027 allows it to be packaged in the industry standard 16-pin dual inline package, which provides the highest system bit densities and is compatible with widely available automated handling equipment.

The use of the 16-pin package is made possible by multiplexing the 12 address bits (required to address 1 of 4096 bits) into the 4027 on 6 address input pins. The two 6-bit address words are latched into the device by the 2TTL clocks, Row Address Strobe ($\overline{RAS}$), and Column Address Strobe ($\overline{CAS}$). Non-critical clock timing requirements allow use of the multiplexing technique while maintaining high performance.



The single transistor dynamic storage cell provides high speed along with low power dissipation. The memory cell requires refreshing for data retention, and this is most easily accomplished by performing a read cycle at each of the 64 row addresses every 2ms, or by performing a $\overline{RAS}$ only cycle.

FEATURES



- **All inputs including clock TTL compatible**
- **On chip latches for address, chip select and data in**
- **3-state TTL compatible output**
- **Output data is latched and valid into next cycle**
- **Access time:**
  - **4027-2: 150ns**
  - **4027-3: 200ns**
  - **4027-4: 250ns**
- **Read and write cycle time:**
  - **4027-2: 320ns**
  - **4027-3: 375ns**
  - **4027-4: 375ns**
- **Low power:**
  - **Operating: 462mW**
  - **Standby: 27mW**
- **RAS only refresh (no dummy cycles required)**
- **Page mode addressing**
- **±10% power supply margins**

PIN CONFIGURATION

F,I,N PACKAGE

BLOCK DIAGRAM

©IC MASTER 1979

FEATURES

- **Full line of bipolar RAMs**
- **Military and commercial temperature ranges**
- **On-chip address latches**
- **2 port memories**
- **Read-while-write memory**
- **PNP inputs for low current**
- **Schottky clamped**
- **TTL compatible**

DESCRIPTION

The 82SXXX family of bipolar RAMs offers one of the widest selection of memories available in the industry. Along with all the standard RAMs, special features have been integrated on many devices enhancing their application effectiveness. Such features as address latches, output latches, 2 port memories and 8 and 9 bit outputs allow this family to answer almost every need.

Also, both commercial and military temperature ranges are available. For commercial range (0°C to +75°C) specify N82SXXX, and for military range (−55°C to +125°C) specify S82SXXX.

NOTES
1. All voltage values are with respect to network ground terminal.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Test each input one at a time.
4. Measured with the logic low stored. Output sink current is supplied through a resistor to V_{CC}.
5. Measured with V_{IH} applied to $\overline{CE}$.
6. I_{CC} is measured with the write enable and memory enable input grounded, all other inputs at 4.5V, and the outputs open.
7. Minimum required to guarantee a Write into the slowest bit.
8. The operating ambient temperature ranges are guaranteed with transverse air flow exceeding 400 linear feet per minute and a 2-minute warm-up.
9. For more detailed specifications, see Signetics data sheet.
10. Package type: N = Plastic, F = Cerdip, I = Ceramic
11. Output definition: OC = Open-collector, TS = 3-state, T = transparent, B = Blanking, C = Common

MEMORY TIMING DEFINITIONS

T_{AA} Delay between beginning of valid Address (with Chip Enable low) and when Data Output becomes valid.

T_{CE} Delay between beginning of Chip Enable low (with Address valid) and when Data Output becomes valid.

T_{WP} Width of Write Enable pulse.

WRT CYCLE Defines the minimum amount of time required to perform a write. This is the sum of T_{WP}(min) plus the minimum address set-up (T_{WSA}) and hold (T_{WHA}) time.

SIGNETICS GENERIC BIPOLAR PROM FAMILY

FEATURES

- **Largest generic PROM family**
- **PNP inputs for low input current**
- **Compatible pin configurations for upward expansion**
- **On-chip output latches**
- **Schottky and Low-Power Schottky PROMs**
- **3-state and open-collector outputs**
- **Fully TTL compatible**
- **Reliability proven Ni-Cr fuses**

DESCRIPTION

The 82SXXX-series generic PROM family offers a wide selection of memory size and organization. The 4-bit wide PROMs range in capacity from 256 words to 2048 words and are packaged in a space saving 16 or 18-pin package. The 8-bit PROMs range in organization from 32 × 8 to 2048 × 8 and are available in a wide selection of package sizes. All PROMs have the same programming specifications allowing a single programmer to program the entire family.

The family also provides low current PNP inputs, both Schottky and low-power Schottky clamping, on-chip latches, and open-collector or 3-state outputs. All PROM fuse links store a low and are programmed to a high.

The entire family is available in both commercial and military temperature ranges. For commercial range (0°C to +75°C) specify N82SXXX, or for military range (−55°C to +125°C) specify S82XXX.

NOTES
1. Positive current is defined as into the terminal referenced.
2. Typical values are at $V_{CC} = 5.0V$, $T_A = +25°C$.
3. All voltage values are with respect to network ground terminal.
4. Applies only to the 82S114/115/182/183.
5. Test one pin at a time.
6. Duration of short-circuit should not exceed 1 second.

©IC MASTER 1979

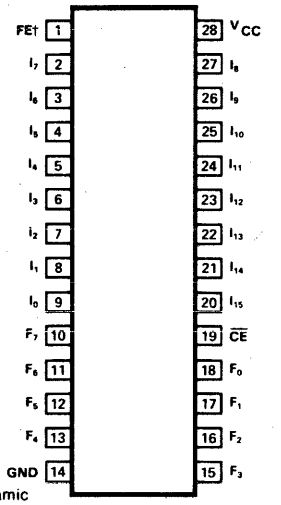
DESCRIPTION

The 82S100 (tri-state outputs) and the 82S101 (open collector outputs) are Bipolar Programmable Logic Arrays, containing 48 product terms (AND terms), and 8 sum terms (OR terms). Each OR term controls an output function which can be programmed either true active-high (Fp), or true active-low ($F\dot{p}$). The true state of each output function is activated by any logical combination of 16-input variables, or their complements, up to 48 terms. Both devices are field programmable, which means that custom patterns are immediately available by following the fusing procedure outlined in this data sheet.

The 82S100 and 82S101 are fully TTL compatible, and include chip-enable control for expansion of input variables, and output inhibit. They feature either open collector or tri-state outputs for ease of expansion of product terms and application in bus-organized systems.

Both devices are available in commercial and military temperature ranges. For the commercial temperature range (0°C to +75°C) specify N82S100/101,I or N, and for the military temperature range (-55°C to +125°C) specify S82S100/101,I.

FEATURES



- **Field programmable (Ni-Cr link)**
- **Input variables: 16**
- **Output functions: 8**
- **Product terms: 48**
- **Address access time:**
  S82S100/101—80ns Max
  N82S100/101—50ns Max
- **Power dissipation: 600mW typ**
- **Input loading:**
  S82S100/101: -50μA Max
  N82S100/101: -100μA Max
- **Chip enable input**
- **Output option:**
  82S100: Tri-state
  82S101: Open collector
- **Output disable function:**
  Tri-state—Hi-Z
  Open collector—Hi

APPLICATIONS

- **CRT display systems**
- **Random logic**
- **Code conversion**
- **Peripheral controllers**
- **Function generators**
- **Look-up and decision tables**
- **Microprogramming**
- **Address mapping**
- **Character generators**
- **Sequential controllers**
- **Data security encoders**
- **Fault detectors**
- **Frequency synthesizers**

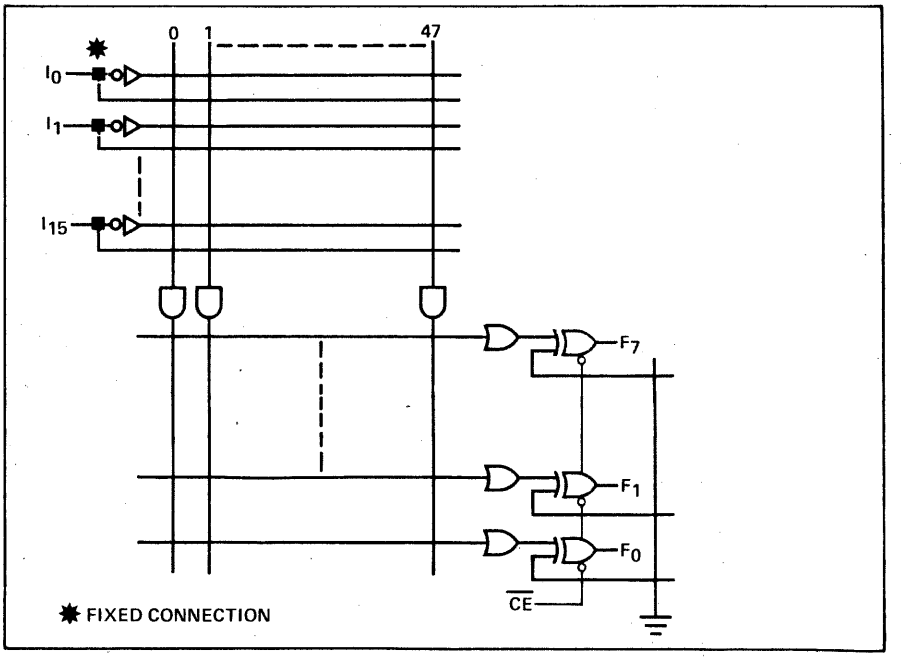
FPLA EQUIVALENT LOGIC PATH

LOGIC FUNCTION



Typical Product Term:
$P_0 = I_0 \bullet I_1 \bullet \overline{I_2} \bullet I_5 \bullet \overline{I_{13}}$

Typical Output Functions:
$F_0 = (\overline{CE}) + (P_0 + P_1 + P_2)$ @ S = Closed
$F_0^* = (\overline{CE}) + (\overline{P_0} \bullet \overline{P_1} \bullet \overline{P_2})$ @ S = Open

NOTE

For each of the 8 outputs, either the function Fp (active-high) or $F\dot{p}$ (active low) is available, but not both. The required function polarity is programmed via link (S).

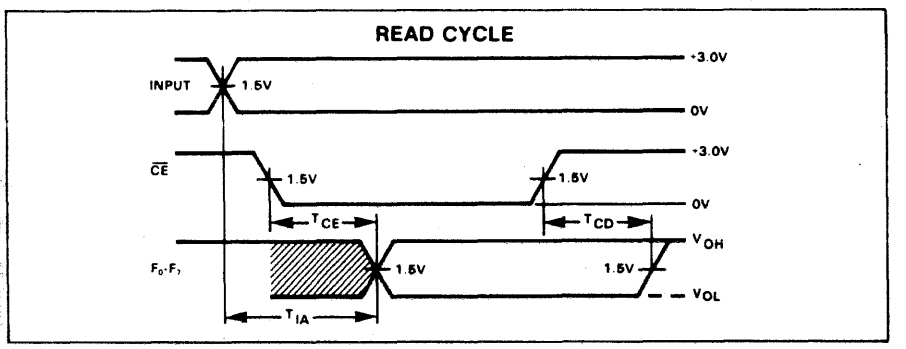
NOTES

1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device of these or any other condition above those indicated in the operation of the device specifications is not implied.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. All voltage values are with respect to network ground terminal.
4. Test one at the time.
5. Measured with V_{IL} applied to $\overline{CE}$ and a logic high stored.
6. Measured with a programmed logic condition for which the output test is at a low logic level. Output sink current is applied thru a resistor to V_{CC}.
7. Measured with: V_{IH} applied to $\overline{CE}$.
8. Duration of short circuit should not exceed 1 second.
9. I_{CC} is measured with the chip enable input grounded, all other inputs at 4.5V and the outputs open.

TEST LOAD CIRCUIT



VOLTAGE WAVEFORM

Measurements: All circuit delays are measured at the +1.5V level of inputs and outputs.

TIMING DIAGRAM

TIMING DEFINITIONS

T_{CE} Delay between beginning of Chip Enable low (with Address valid), and when Data Output becomes valid.

T_{CD} Delay between when Chip Enable becomes high and Data Output is in off state (Hi-Z or high).

T_{IA} Delay between beginning of valid Input (with Chip Enable low) and when Data Output becomes valid.

©IC MASTER 1979

DESCRIPTION

The 82S102 and 82S103 are Bipolar programmable AND/NAND gate arrays, containing 9 gates sharing 16 common inputs. On-chip input buffers enable the user to individually program for each gate either the True (I_m), Complement ($\overline{I_m}$), or Don't Care (X) logic state of each input. In addition, the polarity of each gate output is individually programmable to implement either AND or NAND logic functions.

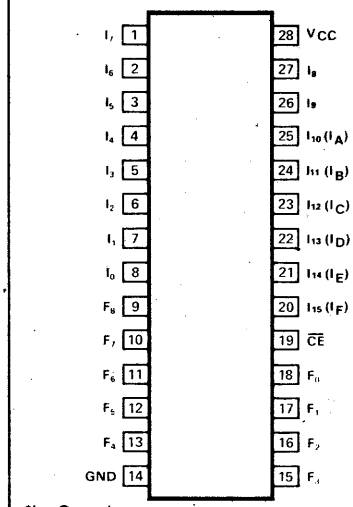
Alternately, if desired, OR/NOR logic functions can also be realized by programming for each gate the complement of its input variables, and output (DeMorgan theorem).

Both devices are field-programmable, which means that custom patterns are immediately available by following the fusing procedure outlined in this data sheet.

The 82S102 and 82S103 include chip-enable control for output strobing and inhibit. They feature either open collector or tri-state outputs for ease of expansion of input variables and application in bus-organized systems.

Both devices are available in the commercial and military temperature ranges. For the commercial range (0°C to +75°C) specify N82S102/103, I or N, and for the military range (-55°C to +125°C) specify S82S102/103, I.

FEATURES



- **Field programmable (Ni-Cr link)**
- **16 input variables**
- **9 output functions**
- **Chip enable input**
- **I/O propagation delay:**
  N82S102/103: 35ns max
  S82S102/103: 50ns max
- **Power dissipation: 600mW typ**
- **Input loading:**
  N82S102/103: -100μA max
  S82S102/103: -150μA max
- **Output options:**
  82S102: Open collector
  82S103: Tri-state
- **Output disable function:**
  82S102: Hi
  82S103: Hi-Z
- **Fully TTL compatible**

APPLICATIONS

- **Random logic**
- **Address decoders**
- **Code detectors**
- **Peripheral selectors**
- **Fault monitors**
- **Machine state decoders**

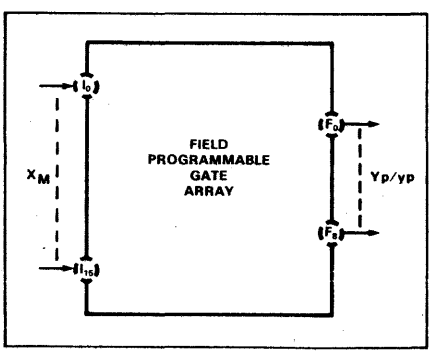
EQUIVALENT LOGIC PATH

The Field Programmable Gate Array consists of 9 gates with individually programmable inputs and outputs.

The inputs to each gate can be programmed either True (I_m), Complement ($\overline{I_m}$), or Don't Care via corresponding links (j) and (k). The outputs of each gate can be programmed active-high (F_p) or active-low (F_p^*) via corresponding links (S). Thus, each gate provides either of 2 output logic functions in terms of *external* input logic variables X_m as defined below (positive logic):



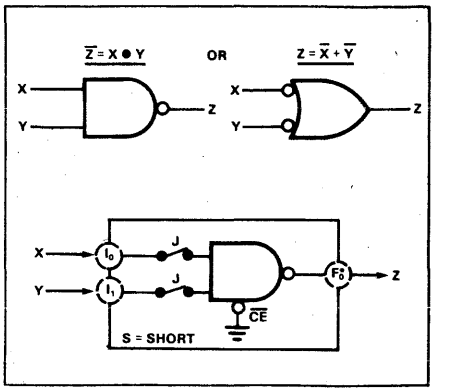
At S = Open:

$F_P = \overline{CE} + (X_0 \bullet X_1 \bullet X_2 \bullet \ldots . X_m) = Y_P$

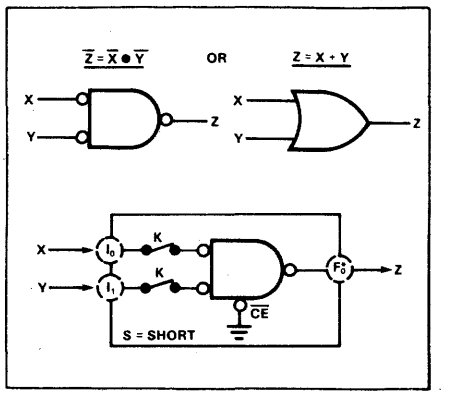
At S = Closed:

$F_P^* = \overline{CE} + (\overline{X}_0 + \overline{X}_1 + \overline{X}_2 + \ldots . X_m) = y_P$

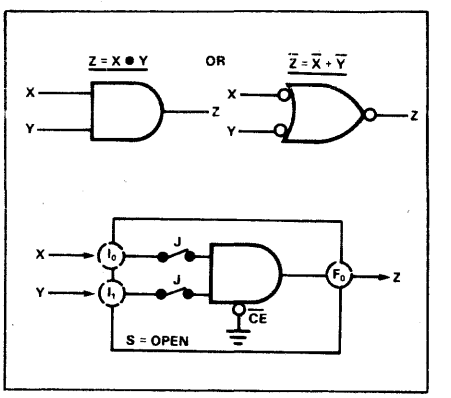
$m = 0, 1, 2, \ldots . 15$



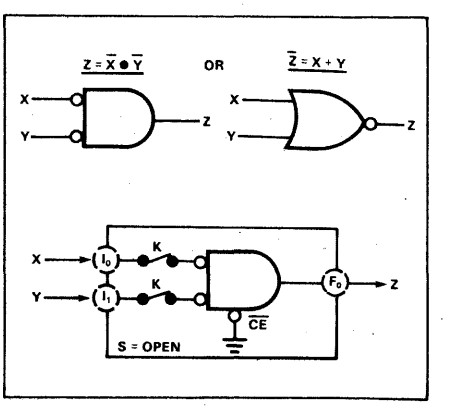
$p = 0, 1, 2, \ldots . 8$



and where $X_m = I_m, \overline{I_m}$, Don't Care, as assigned by programming polarity of inputs I_0–I_{15}.



When $\overline{CE}$ = low, all gates are enabled, and $F_P^* = \overline{F}_P$ giving $y_P = \overline{Y}_P$.



PROGRAMMABLE LOGIC FUNCTIONS

All internal links of virgin FPGAs are intact. Therefore, as shown in the Equivalent Logic Path, all symbolic switches are initially closed. Selective programming (opening) of links (J), (K), and (S) enables the user to assign input and output polarities to each gate for implementing NAND, NOR, AND, OR logic functions without changing the routing of input and output wires. This is shown in the following diagrams for a typical gate in terms of 2 input variables, which can be readily extended up to 16.

NOTES

1. All voltage values are with respect to network ground terminal.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Test each output one at a time.
4. Measured with a programmed logic condition for which the output under test is at a low logic level. Output sink current is supplied through a resistor to V_{CC}.
5. Measured with V_{IL} applied to $\overline{CE}$ and a logic high at the output.
6. Measured with V_{IH} applied to $\overline{CE}$.
7. Duration of short circuit should not exceed 1 second.
8. I_{CC} is measured with the chip enable input grounded, all other inputs at 4.5V and the outputs open.

TEST LOAD CIRCUIT

VOLTAGE WAVEFORM

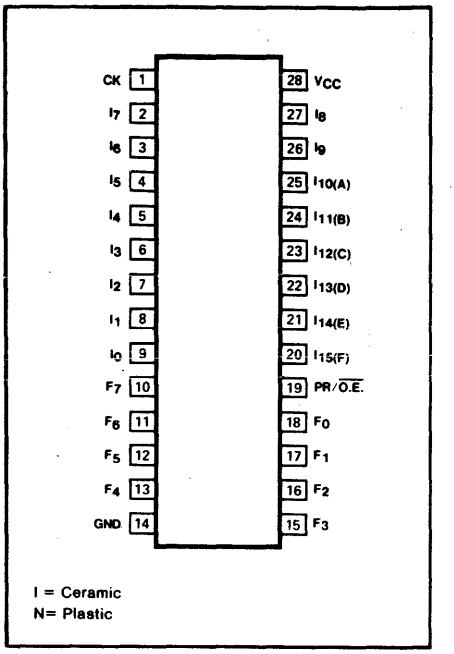
©IC MASTER 1979

DESCRIPTION

The 82S104 (open collector outputs) and the 82S105 (tri-state outputs) are bipolar, programmable state machines of the Mealy type. They contain logic AND-OR gate arrays with user programmable connections which control the inputs of on-chip State and Output registers. These consist respectively of 6 Q_S, and 8 Q_f edge triggered, clocked S/R flip-flops, with asynchronous Preset option. All flip-flops are unconditionally preset to "1" during power turn on.

The AND array combines 16 external inputs $I_{0\text{-}15}$ with 6 internal inputs $Q_{0\text{-}5}$ fed back from the State register to form up to 48 Transition terms (AND terms). All Transition terms can include True, False, or Don't Care states of the controlling variables, and are merged in the OR array to issue next-state and next-output commands to their respective registers on the Low to High transition of the Clock pulse. Both True and Complement Transition terms can be generated by optional use of the internal input variable (C) from the Complement array. Also, if desired, the Preset input can be converted to Output-Enable function, as an additional user programmable option.

Both devices are available in commercial and military temperature ranges. For the commercial temperature range (0°C to +75°C) specify N82S104/105, I or N, and for the military temperature range (−55°C to +125°C) specify S82S104/105, I.



TRUTH TABLE (Output Control)

I_O	INPUT OPTION		F_N
	PR	$\overline{O.E.}$	
X	H		H
+10	L		Q_S
X		H	H/Hi-Z
X		L	Q_F
+10		L	Q_S

NOTES

1. Positive Logic:
   $S/R = T_O + T_1 + T_2 \ldots T_{47}$
   $T_n = C \bullet (I_O \bullet i_1 \bullet i_2 \ldots) \bullet (P_O \bullet P_1 \ldots P_5)$
   C, I_m, P_s = High, Low or Don't Care
2. Either Preset (active-High) or Output Enable (active-Low) are available, but not both. The desired function is a user programmable option.
3. ↑ denotes transition from Low to High level.
4. R = S = High is an illegal input condition.

BLOCK DIAGRAM

NOTE: I, P, N, F, and P/E are user programmable connections.

FEATURES

- Field programmable (Ni-Cr link)
- 16 input variables
- 8 output functions
- 48 transition terms
- 6-BIT state register
- 8-BIT output register
- Transition complement array
- Positive edge trigger clock
- Programmable asynchronous preset or output enable
- Power-on preset to all "1" of internal Registers
- 90 Ns maximum I/O delay
- 650mW power dissipation (typical)
- TTL compatible
- SINGLE +5V supply

APPLICATIONS

- Interface protocols
- Sequence detectors
- Peripheral controllers
- Timing generators
- Sequential circuits
- Elevator controllers
- Security locking systems

82S106-I,N • 82S107-I,N

DESCRIPTION

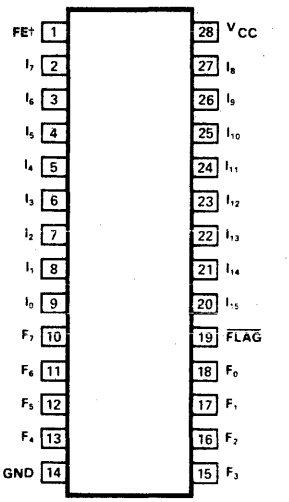
The 82S106 (Open collector outputs) and 82S107 (3-state outputs) are bipolar Programmable ROM Patches organized as 48 words by 8 bits, addressed via a 16 bit programmable address comparator. Each word can be assigned a unique address code, P_n, within a 64K (2^{16}) address range by programming the comparator inputs High, Low, or Don't care via True/Complement input buffers.

The contents of each word are also programmable, and are enabled to the active-High Patch outputs only when a programmed address is detected, which causes the $\overline{\text{Flag}}$ output to go Low. For all unprogrammed addresses, the device outputs remain High (82S106) or Hi-Z (82S107) while the $\overline{\text{Flag}}$ output remains High. The $\overline{\text{Flag}}$ is open collector to allow wire-ANDing for expansion to more than 48 patch words.

The 82S106 and 82S107 are fully TTL compatible and can be programmed in the field by following the fusing procedure outlined in this data sheet, or by means of commercially available equipment.

Both devices are available in commercial and military temperature ranges. For the commercial range (0°C to +75°C) specify N82S106/107, I or N, and for the military temperature range (-55°C to +125°C) specify S82S106/107, I.

FEATURES



- **Field programmable (Ni-Cr link)**
- **Address Inputs: 16**
- **Data Outputs: 8**
- **Patch Words: 48**
- **Address access time:**
  S82S106/107—100ns Max
  N82S106/107—70ns Max
- **Power dissipation: 600mW typ**
- **Input loading:**
  S82S106/107: -150μA Max
  N82S106/107: -100μA Max
- **Open collector $\overline{\text{Flag}}$**
- **Output option:**
  82S106: Open collector
  82S107: 3-state
- **Output disabled state**
  3-state—Hi-Z
  Open collector—Hi

APPLICATIONS

- **ROM data modifications**
- **Memory address trap**
- **Digital filter**
- **Interrupt request/vector generator**
- **Data security encoder**

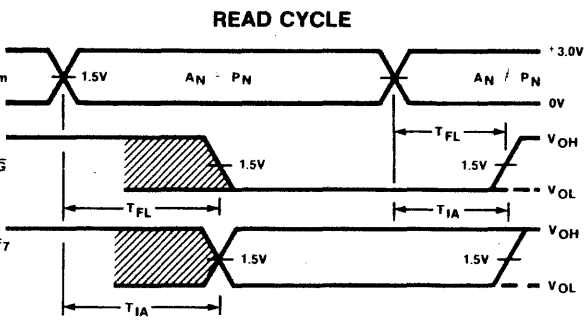
NOTES

1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device of these or any other condition above those indicated in the operation of the device specification is not implied.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. All voltage values are with respect to network ground terminal.
4. Test one at the time.
5. Measured with the Patch enabled ($A_N = P_N$) and a logic high stored.
6. Measured with a programmed logic condition for which the output under test is at a low logic level when the Patch is enabled ($A_N = P_N$). Output sink current is applied thru a resistor to V_{CC}.
7. Measured with the Patch disabled ($A_N \neq P_N$).
8. Duration of short circuit should not exceed 1 second.
9. I_{CC} is measured with all inputs at 4.5V and the outputs open.

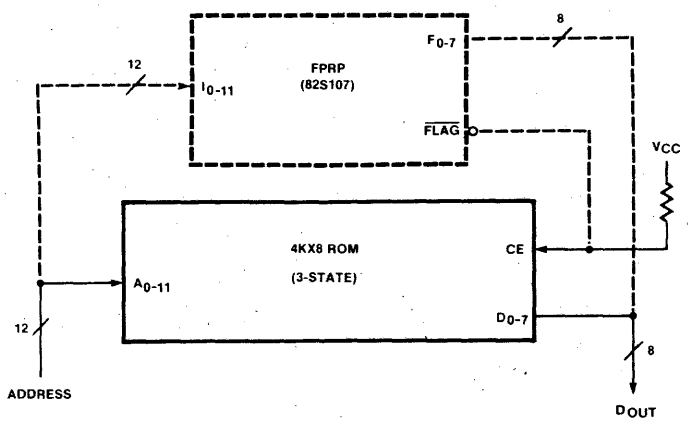
TEST LOAD CIRCUIT



VOLTAGE WAVEFORM

Measurements: All circuit delays are measured at the +1.5V level of inputs and outputs.

TIMING DIAGRAM



TIMING DEFINITIONS

T_{IA} Delay between latest Address variable change and when Data Output becomes stable.

T_{FL} Delay between latest Address variable change and when $\overline{Flag}$ output becomes stable.

Since Patch inputs I_{12-15} are unused, they are programmed Don't Care (–), and left open in the circuit. Note however that I_0 and I_1 are programmed as (–) in P-term 2 because they define an address block of 4 memory locations.

EXPANSION

When more than 48 memory locations need to be patched, several devices can be paralleled by wire-ANDing the $\overline{Flag}$ outputs.

82LS180-F,N • 82LS181-F,N

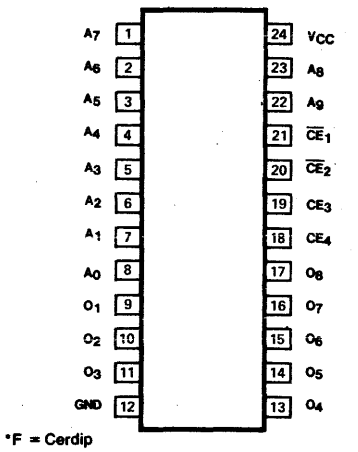
DESCRIPTION

The 82LS180 and 82LS181 are field programmable, which means that custom patterns are immediately available by following the fusing procedure given in this data sheet. The standard 82LS180 and 82LS181 are supplied with all outputs at logical low. Outputs are programmed to a logic high level at any specified address by fusing a Ni-Cr link matrix.

These devices include on-chip decoding and 4 chip enable inputs for ease of memory expansion. They feature either open collector or 3-state outputs for optimization of word expansion in bused organizations.

The 82LS180 and 82LS181 are available in both the commercial and military temperature ranges. For the commercial temperature range (0°C to +75°C) specify N82LS180/181, F or N, and for the military temperature range (−55°C to +125°C) specify S82LS180/181, F.

FEATURES



- **Address access time:**
  N82LS180/181: 175ns max
  S82LS180/181: 225ns max
- **Power dissipation: 37μW/bit typ**
- **Input loading:**
  N82LS180/181: −100μA max
  S82LS180/181: −150μA max
- **On-chip address decoding**
- **Output options:**
  82LS180: Open collector
  82LS181: 3-state
- **No separate fusing pins**
- **Unprogrammed outputs are low level**
- **Fully TTL compatible**

APPLICATIONS

- **Prototyping/volume production**
- **Sequential controllers**
- **Microprogramming**
- **Hardwired algorithms**
- **Control store**
- **Random logic**
- **Code conversion**

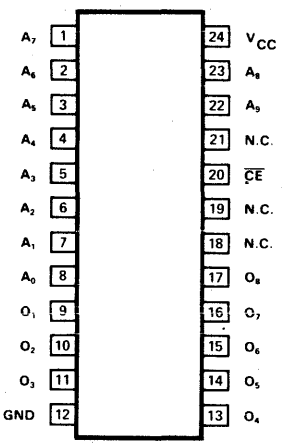
82S2708-F

DESCRIPTION

The 82S2708 is field programmable, which means that custom patterns are immediately available by following the fusing procedure given in this data sheet. The standard 82S2708 is supplied with all outputs at logical low. Outputs are programmed to a logic high level at any specified address by fusing a Ni-Cr link matrix.

This device includes on-chip decoding and 1 chip enable input for ease of memory expansion. It features tri-state outputs for optimization of word expansion in bused organizations.



The 82S2708 is available only in the military temperature range. For the military temperature range (-55°C to +125°C) specify S82S2708.

FEATURES

- **Address access time:**
  S82S2708: 90ns max
- **Power dissipation: 85μW/bit typ**
- **Input loading:**
  S82S2708: -150μA max

SUPER HIGH SPEED 256 BIT TTL PROGRAMMABLE READ ONLY MEMORY

Preliminary January 1979

FEATURES

- Electrically Programmable—Fuse Link
- High Speed—Schottky clamped
- Address Access—15 ns max.
- Enable Access—10 ns max.
- DTL/TTL Compatible
- Board Level Programming

Pin-Outs

DESCRIPTION

These are super high speed Schottky TTL programmable read-only Memories, organized in 32 word by 8 bit configuration. They are fully TTL input/output compatible and operate over commercial and military voltage and temperature ranges. The logic levels are "zero"s when low and "one"s when high. It can be electrically programmed in selected bit locations. All the address inputs can be used for programming and reading.

They are both available in open collector (SM 74S188 and MM 74S188) and tri-state (SM 74S288 and MM 74288) output versions.

APPLICATIONS

High Speed Logic Substitution and High Speed Programmable Logic Array

16,384 BIT TTL PROGRAMMABLE READ-ONLY MEMORY

Preliminary January 1979

FEATURES

- Fast Access Times: 40 nsec typical
- Temperature compensating for wide range of operation
- Low Voltage Programming
- Board Level Programming
- Highly reliable fuses for ultra-fast programming
- Pin for Pin replacement of Industry Standard
- Fully TTL compatible.

Pin-Outs

GENERAL DESCRIPTION

These are Memories organized in 2048 word by 8 bit configuration. The 82S190/191 are field programmable devices. This means that the desired patterns are available by following the programming procedure. These PROM's are shipped in unprogrammed forms. They have Low's in all locations. The Logical High is achieved by blowing open the fuses at the selected locations. After fusing, the state of the programming is irreversible.

These PROM's use a Supertex Proprietary Schottky Technology. This innovation makes it possible to produce a very small cell size. The design also incorporates advanced circuit and decoding techniques which contribute to the fast access times.

These devices are available with Open Collector 82S190 and Tri-State 82S191 outputs. Both of them are available in the commercial and military ranges.

OPERATING RANGES AND ACCESS TIMES

SM82S190/SM82S191	0°C to +75°C	V_{CC} = 5.0V ± 5%	t_{AA} (typ.) = 40 nsec
MM82S190/MM82S191	−55°C to +125°C	V_{CC} = 5.0V ± 10%	t_{AA} (typ.) = 50 nsec
			t_{EA} (typ.) = 20 nsec

APPLICATIONS

Microprogramming, Hardwired Algorithms, Control Store, Random Logic, Code Conversion, and Sequential Controllers.

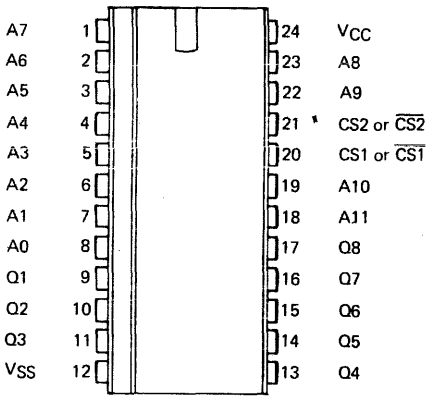
CM3200



32,768 BIT STATIC CMOS READ-ONLY MEMORY

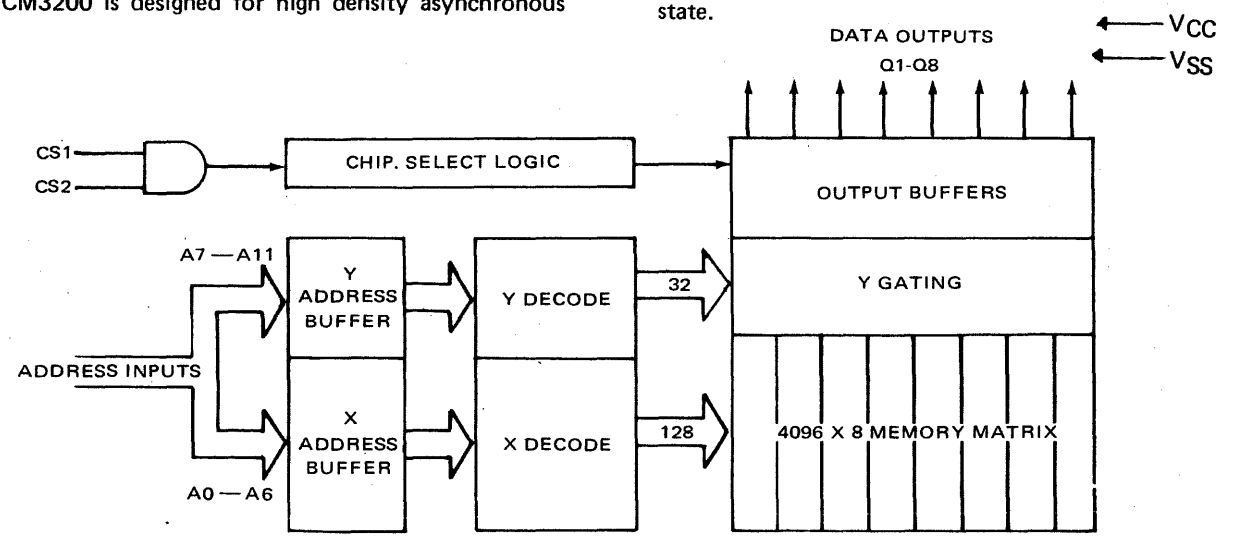
Preliminary December 1978

FEATURES

- 4096 x 8 Organization
- All Inputs and Outputs TTL Compatible
- Fully Static—No clocks or refresh
- Single 5V Power Supply
- Maximum Access Time . . . 450 ns
- Minimum Cycle Time . . . 450 ns
- Typical Operating Power Dissipation . . . 10mW/MHz
- 3-State Outputs for OR-ties
- Industry Standard Pin Configuration . . . Pin Compatible with Intel 2708, Intel 8316B, TMS 2708
- Two programmable Chip Select Inputs
- Low power CMOS Technology
- Typical Standby Power Dissipation . . . 50 uW total or 1.5 nW/bit

24-Pin Ceramic and Plastic Dual-in-Line Packages (Top View)

DESCRIPTION



The CM3200 is a 32,768 bit read-only memory organized in 4096 word by 8 bit configuration. Low power, low cost CMOS technology and advanced circuit design makes the CM3200 ideal for microprocessor based or battery operated systems. The device operates at high speed and interface simply with TTL circuits, does not require any clock input, and yet consumes very little operating or standby power.

All inputs can be driven directly by Series 74 TTL circuits or 4000 series CMOS circuits without any external components. Each output can drive one standard TTL load. The data outputs are three-state and allows multiple devices or-tied on a common bus. Two TTL compatible chip select inputs allow easier memory expansion.

The CM3200 is designed for high density asynchronous fixed Memory applications such as look-up logic tables and microprogramming. Industry standard pin out configuration makes it very easy to replace four 8K EPROMS, two 16K ROMS or one 32K ROM for lower power dissipation and lower cost.

The CM3200 is available in 24-pin dual-in-line plastic or ceramic packages.

The 12 address inputs are decoded on-chip and selects one of 4096 word of 8 bit data. Each of the two chip select inputs are programmable to be either active high or active low level. When both chip select inputs are active, the eight outputs are enabled. When either chip select input is not active, all the eight outputs are in a high-impedance state.

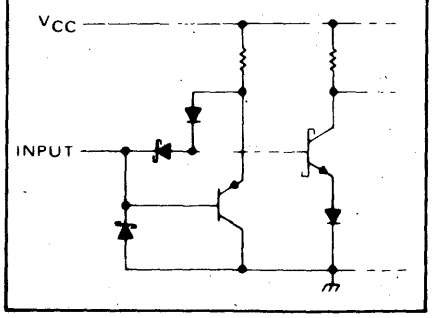
description (continued)

Data can be electronically programmed, as desired, at any bit location in accordance with the programming procedure specified. All PROM's, except the 'S287 and 'S387 are supplied with a low-logic-level output condition stored at each bit location. The programming procedure open-circuits Ti-W metal links, which reverses the stored logic level at selected locations. The procedure is irreversible; once altered, the output for that bit location is permanently programmed. Outputs never having been altered may later be programmed to supply the opposite output level. Operation of the unit within the recommended operating conditions will not alter the memory content.



Active level(s) at the chip-select input(s) enables all of the outputs. An inactive level at any chip-select input causes all outputs to be off.

The three-state output offers the convenience of an open-collector output with the speed of a totem-pole output; it can be bus-connected to other similar outputs yet it retains the fast rise time characteristic of the TTL totem-pole output. The open-collector output offers the capability of direct interface with a data line having a passive pull-up.

NOTES: 1. Voltage values are with respect to network ground terminal. The supply voltage rating does not apply during programming.
2. The 'S188, 'S288, 'S470, 'S471, 'S472, 'S473, 'S474, and 'S475 are supplied with all bit locations containing a low logic level, and programming a bit changes the output of the bit to high logic level. The 'S287 and 'S387 are supplied with all bit outputs at a high logic level, and programming a bit changes it to a low logic level.
3. Programming is guaranteed if the pulse applied is 98 μs in duration.

©IC MASTER 1979

step-by-step programming procedure for the 'S188, 'S287, 'S288, 'S387, 'S470 through 'S475

1. Apply steady-state supply voltage (V_{CC} = 5 V) and address the word to be programmed.
2. Verify that the bit location needs to be programmed. If not, proceed to the next bit.
3. If the bit requires programming, disable the outputs by applying a high-logic-level voltage to the chip-select input(s).
4. Only one bit location is programmed at a time. Connect each output not being programmed to 5 V through 3.9kΩ and apply the voltage specified in the table to the output to be programmed. Maximum current out of the programming output is 150 mA. This current flows from the programmer into the PROM output.
5. Step V_{CC} to 10.5 V nominal. Maximum supply current required during programming is 750 mA.
6. Apply a low-logic-level voltage to the chip-select input(s). This should occur between 1 μs and 1 ms after V_{CC} has reached its 10.5-V level. See programming sequence of Figure 2.
7. After the X pulse time is reached, a high logic level is applied to the chip-select inputs to disable the outputs.
8. Within 1 μs to 1 ms after the chip-select input(s) reach a high logic level, V_{CC} should be stepped down to 5 V at which level verification can be accomplished.
9. The chip-select input(s) may be taken to a low logic level (to permit program verification) 1 μs or more after V_{CC} reaches its steady-state value of 5 V.
10. At a Y pulse duty cycle of 35% or less, repeat steps 1 through 8 for each output where it is desired to program a bit.

NOTE: Only one programming attempt per bit is recommended.

- Titanium-Tungsten (Ti-W) Fuse Links for Fast, Low-Voltage, Reliable Programming
- All Schottky-Clamped PROM's Offer:
  - Fast Chip Select to Simplify System Decode
  - Choice of Three-State or Open-Collector Outputs
  - P-N-P Inputs for Reduced Loading on System Buffers/Drivers
- Full Decoding and Chip Select Simplify System Design
- Applications Include:
  - Microprogramming/Firmware Loaders
  - Code Converters/Character Generators
  - Translators/Emulators
  - Address Mapping/Look-Up Tables

Pin assignments for all of these memories are the same for all packages.

description

These monolithic TTL programmable read-only memories (PROM's) feature titanium-tungsten (Ti-W) fuse links with each link designed to program with a 100 microsecond pulse. These PROM's offer considerable flexibility for upgrading existing designs or improving new designs as they feature full Schottky clamping for improved performance, low-current MOS-compatible p-n-p inputs, choice of bus-driving three state or open-collector outputs, and improved chip-select access times.

The high-complexity 2048- and 4096-bit 20-pin PROM's can be used to significantly improve system density for fixed memories as all are offered in dual-in-line packages having pin-row spacings of 0.300 inch.

PRELIMINARY DATA SHEET: Supplementary data may be published at a later date.

	Pulse width, t_w	1000		2000	μs
	Duty cycle		25	35	%
$\overline{S}$, $\overline{S1}$ or $\overline{S2}$ programming pulse (see Figure 1)	Voltage, $V_{\overline{S}(pr)}$	9.75	10	11	V
	V_{IL}	0		0.5	
Output programming pulse (see Figure 1)	Voltage, $V_{O(pr)}$	16.75	17	17.25	V
	Rise time, t_r	10		50	μs
	Pulse width, t_w	98	100	1000	μs
	V_{IL}	0		0.5	
Free-air temperature, T_A		0		55	°C

step-by-step programming instructions (see Figure 1)

1. Address the word to be programmed, apply 5 V ± 10% to V_{CC} and active levels to all chip select (S and $\overline{S}$) inputs.
2. Verify the status of a bit location by checking the output level.
3. Increase V_{CC} to $V_{CC(pr)}$ with a minimum current capability of 200 milliamperes.
4. Apply $V_{\overline{S}(pr)}$ to all the $\overline{S}$ inputs. $I_I \leqslant 5$ mA.
5. Connect all outputs, except the one to be programmed, to a logic low level ($0 \leqslant V_{IL} \leqslant 0.5$ V). Only one bit is programmed at a time.
6. Apply the output programming pulse for at least 98 microseconds. Minimum current capability of the programming supply should be 200 milliamperes.
7. After terminating the output pulse, disconnect all outputs from V_{IL} conditions.
8. Reduce the voltage at $\overline{S}$ inputs to V_{IL}.
9. Reduce V_{CC} to steady-state voltage and verify output status.
10. Repeat Steps 3 thru 9 for each bit location that requires programming. Only one programming attempt per bit is recommended.
11. Verify accurate programming of every word after all words have been programmed using V_{CC} values of 4.5 and 5.5 volts.

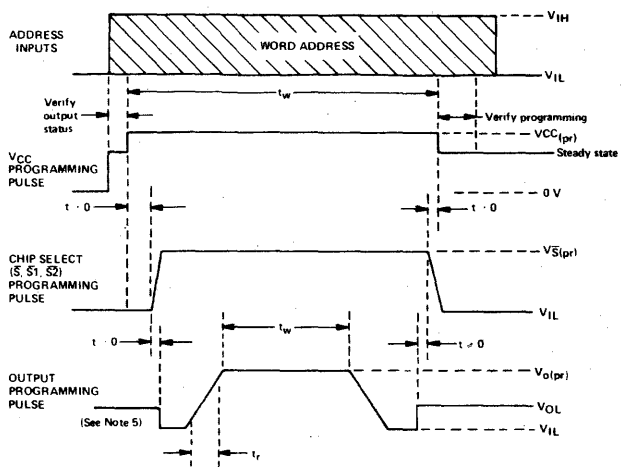

FIGURE 1–TIMING DIAGRAM AND VOLTAGE WAVEFORMS FOR PROGRAMMING SEQUENCE

NOTE 5: The output to be programmed may be forced to zero volts after the transition to $V_{O(pr)}$ at the $\overline{S}$ input has begun.

*Electrical parameters for the 'S452, 'S453, 'LS478, 'LS479 are design goals only.

positive logic: see description

description

These synchronous presettable counters feature an internal carry look-ahead for cascading in high-speed counting applications. The 'LS668 are decade counters and the 'LS669 are 4-bit binary counters. Synchronous operation is provided by having all flip-flops clocked simultaneously so that the outputs change coincident with each other when so instructed by the count-enable inputs and internal gating. This mode of operation helps eliminate the output counting spikes that are normally associated with asynchronous (ripple-clock) counters. A buffered clock input triggers the four master-slave flip-flops on the rising (positive-going) edge of the clock waveform.

These counters are fully programmable; that is, the outputs may each be preset to either level. The load input circuitry allows loading with the carry-enable output of cascaded counters. As loading is synchronous, setting up a low level at the load input disables the counter and causes the outputs to agree with the data inputs after the next clock pulse.

The carry look-ahead circuitry provides for cascading counters for n-bit synchronous applications without additional gating. Instrumental in accomplishing this function are two count-enable inputs and a carry output. Both count enable inputs ($\overline{P}$ and $\overline{T}$) must be low to count. The direction of the count is determined by the level of the up/down input. When the input is high, the counter counts up; when low, it counts down. Input $\overline{T}$ is fed forward to enable the carry output. The carry output thus enabled will produce a low-level output pulse with a duration approximately equal to the high portion of the Q_A output when counting up and approximately equal to the low portion of the Q_A output when counting down. This low-level overflow carry pulse can be used to enable successive cascaded stages. Transitions at the enable $\overline{P}$ or $\overline{T}$ inputs are allowed regardless of the level of the clock input. All inputs are diode-clamped to minimize transmission-line effects, thereby simplifying system design.

These counters feature a fully independent clock circuit. Changes at control inputs (enable $\overline{P}$, enable $\overline{T}$, load, up/down) that will modify the operating mode have no effect until clocking occurs. The function of the counter (whether enabled, disabled, loading, or counting) will be dictated solely by the conditions meeting the stable setup and hold times.

The 'LS668 and 'LS669 are completely new designs. Compared to the original 'LS168 and 'LS169, they feature 0-nanosecond minimum hold time, reduced input currents I_{IH} and I_{IL}, and all buffered outputs.

INTRODUCTION TO MICROPROCESSORS

This section describes microprocessors from 32 manufacturers. First, there is the "Master Selection Guide" for microprocessors. A complete survey, it covers all major areas of information needed to choose a microprocessor for a particular application. Next is the "System Components" section. Arranged alphanumerically by microprocessor, it shows all the available peripheral devices that work with a particular microprocessor. Finally, there is a "General Purpose" section describing devices that can be used in different microprocessor systems, not necessarily with one family.

Those manufacturers and page numbers listed below in **BOLD PRINT,** are providing detailed information on the latest and most significant products.

MICROPROCESSOR–System Components

This section presents the major microprocessor system devices organized into system groups, ie F8, 6800, 8080, etc. It includes those RAM's, ROM's and PROM's which are unique to a system. It omits most general purpose memories as they are listed in the Memory section. Similarly, buffers, line drivers, transceivers, UART's, etc. are covered briefly here as they are presented in depth in the Digital and Interface sections.

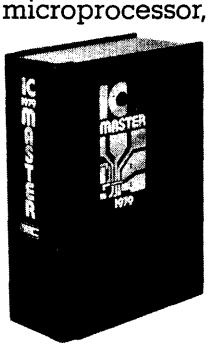
"I need to know if this device exists, and if there are any alternate sources. Where do I start?"

- Memory IC
- RAM
- Static
- 1024x1
- CMOS
- 250 Nanoseconds
- 5 Volts

If you're spending hours to solve a problem similar to the one above, you're behind the times...



It only takes a few seconds with "THE MASTER."

Clear your desk for action with the newly revised 1979 IC Master. Its all-under-one-cover features include: Over 40,000 standard products from more than 87 different companies... five different selection guides (memory, microprocessor, interface, linear and digital.) ... alternate source directory for pin- for- pin, function- for- function replacements ... applications directory... complete military section ... a complete part numbering guide ... etc.

You don't have to search through stacks of catalogs. Simply look up the specs and function you need. You don't need a part number to start with.

All you need is a problem to use The Master. Does the device exist? Who makes it? Is there an alternate source? What's the part number? Is there an applications note? Who is my closest distributor—etc.

S2000 Single-Chip Microcomputer Family

AMI's S2000 family of single-chip microcomputers offers a wide range of capability to the user seeking flexible, adaptable system(s) at low cost. The S2000 family provides the ideal solution to appliance and industrial/process-control applications. With versatile keyboard-oriented inputs, and outputs which can drive either LED or fluorescent displays directly, the S2000 family is designed specifically to minimize system parts count and cost.

Table I. S2000 Family Features

	S2000	S2150	S2200	S2400
ROM (x8)	1K	1.5K	2K	4K
RAM (x4)	64	80	128	128
Interrupts	—	—	3	3
A/D CONV (8 Channel)	—	—	8-Bit	8-Bit
Counter/Timer	÷50/÷60	÷50/÷60	8-Bit	8-Bit
Max Subroutine Levels	3	3	5	5
Instructions	51	51	59	59
Cycle Time (μs)	4.5	4.5	4.5	4.5
High Voltage (Fluorescent Display Drive Version)	S2000A	S2150A	S2200A	S2400A

The S2000 family provides the advantages of computer architecture to low cost, minimum-parts-count display/keyboard oriented control systems.

S2000/2150 Features

- ☐ **1024 x 8 Program ROM On-Chip; Externally Expandable to 8192 x 8 — S2000**
- ☐ **1536 x 8 Program ROM On-Chip; Externally Expandable to 8192 x 8 — S2150**
- ☐ **64 x 4 Scratchpad RAM On Chip — S2000**
- ☐ **80 x 4 Scratchpad RAM On-Chip — S2150**
- ☐ **13 Outputs and Inputs, Plus 8 Bi-Directional Three-State Lines**
- ☐ **Touch Control™ Capacitive Touchplate Interface**
- ☐ **Seconds Timer for Both 60Hz and 50Hz Lines**
- ☐ **7-Segment Decoder and LED Display Drivers On Chip**
- ☐ **Single 9.0 Volt Supply**
- ☐ **Fast 4.5μs Execution Cycle**
- ☐ **Three-Level Subroutine Stack**
- ☐ **TTL-Compatible Outputs**
- ☐ **Reset, Test, and Single Step Modes**
- ☐ **Access to All Internal Registers and Memory for Debug and Test**
- ☐ **Crystal Input for Accurate Clocking — S2150**
- ☐ **Low Power RAM Retention, 20μA/Bit Typ @ 4V — S2150**

S2000A/2150A Vacuum Fluorescent Display

The S2000A/2150A are identical to the S2000/2150 but provide high voltage fluorescent display capability. The output buffer drive (V_{DD}) is changed to a vacuum fluorescent drive (V_{FD}) and typically tied to 32 volts. The D_0 through D_7 and A_0 through A_4 are changed from LED drivers (nominal 5 volts) to vacuum fluorescent drivers (nominal 26 volts).

S2200/2400 Features

The S2200/2400 provide a quantum jump in chip features beyond the S2000. In addition to all the features the S2000 offers, the S2200 gives the added flexibility of interrupts and the sophistication of an on-chip A/D or D/A converter capable of multiplexing 8 channels of analog data making it suitable for a wide range of applications.

- ☐ **2048 x 8 Program ROM On Chip Expandable to 8192 x 8 — S2200**
- ☐ **4096 x 8 Program ROM On-Chip; Externally Expandable to 8192 x 8 — S2400**
- ☐ **128 x 4 Scratchpad RAM On Chip**
- ☐ **RAM Save Power Down Mode (Mask Option)**
- ☐ **Two-Level Maskable Priority Interrupt System with Provision for Software Interrupt**
- ☐ **Programmable 8-Bit Timer/Event Counter On Chip**
- ☐ **13 Outputs, 9 Inputs, Plus 8 Bi-Directional Three-State Lines**
- ☐ **Touch Control™ Capacitive Switch Interface**
- ☐ **7-Segment Display Decoders and LED Drivers**
- ☐ **TTL-Compatible Outputs**
- ☐ **Single +9V Power Supply**
- ☐ **4.5μs Cycle Time**
- ☐ **59 Instructions — 52 Single Byte and Single Cycle**
- ☐ **3-Level Subroutine Stack**
- ☐ **2-Level Interrupt Stack**
- ☐ **Built-In Production Test Mode**
- ☐ **Single-Step Capability**
- ☐ **Power-Fail Detect, RAM Keep-Alive and Power-On Reset Circuitry**

S2000 Family Support

The S2000 single-chip microcomputer family, unlike many microprocessors, does not leave the designer or industrial OEM unsupported. The S2000 Family features a proven array of development aids:

Microcomputer Development Center (MDC) — AMI's MDC is a fully equipped, dual-floppy disk-based microcomputer development facility, complete with FDOS-II Floppy-Disk-Operating and File Management System. Controlled from its CRT terminal, MDC provides instant access to program and data files resident on removable diskettes.

Development Software — The MDC's software includes self-diagnostics and a comprehensive Text Editor and PROM programmer package that support S2000 software development. In addition, S2000 software includes a MACRO Assembler, Loader, and Instruction Simulator.

Cross-Assemblers editor and simulator debug — Available on a major timesharing service.

Logic Analyzer — The MDC-140 Logic Analyzer is an advanced debug tool connected as a peripheral device of the AMI Microcomputer Development Center (MDC). Features include:

- Captures 1024 Events of 40 Parallel Inputs
- Captures Data Under Control of Programmable Start on Data Content
- Delay of −1024 to +64K Clock Periods
- Setup and Display of Captured Data Under Control of MDC Software
- Display Format is User-Definable; Captured Data Can Be Displayed in a Mix of Hex, Octal, Binary, ASCII and Special Formats for Support of S6800, S6820, S2000, 8080, etc.
- Four Clock Sources
- Input Voltage Range = −15 to +15 volts
- Adjustable Input Thresholds
- Data-Dependent Output for Triggering an Oscilloscope

SES-2150(A)/SES-2400(A) — The SES-2150/2400 Emulator boards are pin-for-pin substitutes for S2000 microcomputer family chips. The Emulator Boards use conventional UV erasable PROMs for program storage.

In addition, a specialized module is used to provide emulation of the S2150A/S2400A high voltage vacuum fluorescent display drivers.

Customer Assistance — AMI's S2000 Family Applications Engineering Staff is readily available for consultation regarding any aspects of S2000 Family usage. The AMI staff is also available to discuss any special modifications to the S2000 for high volume applications.

©IC MASTER 1979

S2000 Family Instruction Set Summary

The S2000 and S2150 contain 51 instructions, all single byte, with 49 that are single cycle. The S2200 and S2400 contain 59 instructions, of which 52 are single cycle and single byte.

Nearly all S2000/2150 instructions are common to the entire family, which allows the programmer to develop software expertise and easily move up the S2000 product line.

Register Instructions

S2000/2150	S2200/2400	
LAI X	LAI X	X→ACC, 0≤X≤15; (In S2000/2150 Select I and K Inputs also)
LAB	LAB	BL→ACC
LAE	LAE	E→ACC
XAB	XAB	BL↔ACC
XABU	XABU	BU↔ACC, (IN S2150, BITS 2, 1, AND 0; IN OTHERS, BITS 1 AND 0 ONLY)
XAE	XAE	ACC↔E
LBE Y	LBE Y	Y→BU, E→BL, 0≤Y≤3
LBZ Y	LBZ Y	Y→BU, 0→BL, 0≤Y≤3
LBF Y		Y→BU, 15→BL, 0≤Y≤3
LBEP Y		Y→BU, E+1→BL, 0≤Y≤3
	SRB	1→BA
	RRB	0→BA
	LMDI X+	X(6)→BA, X(5-4)→BU, X(3-0)→BL
	RAR	ACC(I)→ACC(I-1), ACC (0)→CARRY, CARRY→ACC(3)
	XAK	KSR↔ACC
	LANG	ACC→AR (3-0), RAM→AR(7-4)
	LNMA	ACC→NR(3-0), RAM→NR (7-4), THEN NR→BIN
	MOD	ACC→MOD(3-0), RAM→MOD(7-4)
	RBIN	BIN(3-0)→ACC; BIN(7-4)→RAM

RAM Instructions

S2000/2150	S2200/2400	
LAM Y*	LAM Y*	RAM→ACC, BU⊕Y→BU
XC Y*	XC Y*	RAM↔ACC, BU⊕Y→BU
XCI Y*	XCI Y*	ACC↔RAM, BL+1→BL, BU⊕Y→BU SKIP IF BL=0 (AFTER INCREMENT)
XCD Y*	XCD Y*	ACC↔RAM, BL-1→BL, BU⊕Y→BU SKIP IF BL=0 (BEFORE DECREMENT)
STM Z	STM Z	1→RAM BIT Z, 0≤Z≤3
RSM Z	RSM Z	0→RAM BIT Z, 0≤Z≤3
	LMA	ACC→RAM
	STMI Z+	1→RAM BIT Z, 0≤Z≤255, (RAM BANK 1)
	RSMI Z+	0→RAM BIT Z, 0≤Z≤255, (RAM BANK 1)

Input/Output Instructions

S2000/2150	S2200/2400	
INP	IND	D3-D0→ACC, D7-D4→RAM
OUT	OUT	ACC→D3-D0, RAM→D7-D4 (NOT LATCHED)
DISN	DISN	ACC→SEGMENT DECODER→DISPLAY LATCH→D6-D0, CARRY→DISPLAY LATCH→D7
DISB	DISB	ACC→DISPLAY LATCH→D3-D0, RAM→DISPLAY LATCH→D7-D4
MVS	MVS	A-LINE MASTER STROBE LATCH→A LINES
PSH	PSH	PRESET HIGH [BL]→MASTER STROBE LATCH
PSL	PSL	PRESET LOW [BL]→MASTER STROBE LATCH
EUR		(EUROPEAN) SET 50/60Hz AND DISPLAY LATCH POLARITY
	INK	K3-K0→ACC, K7-K4→RAM

+ 8 bits in the second byte of an instruction.

*Assembled code contains complement of those arguments (the assembler does it automatically).

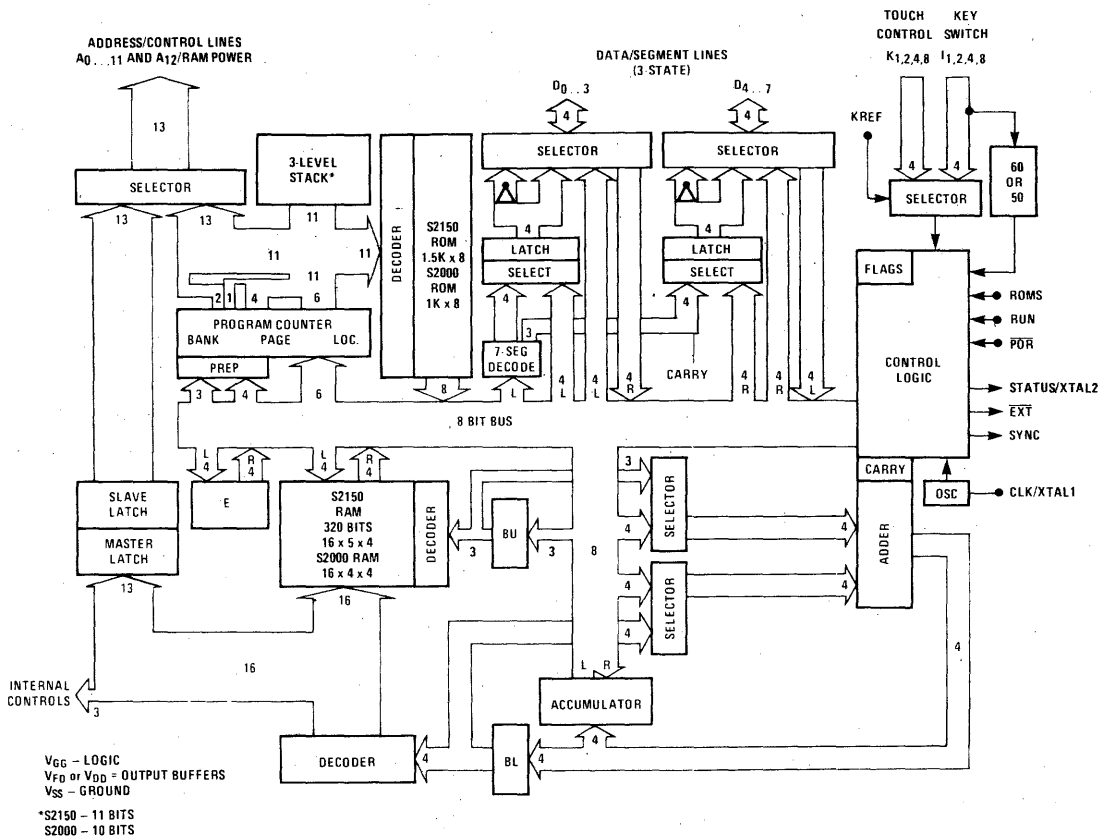
S2000/S2150 and S2200/S2400 Instruction Set Summary

Program Control Instructions

S2000/2150	S2200/2400	
PP X*	PP X*	IF PREVIOUS INSTRUCTION = PP, X→PPR (0≤X≤15) IF PREVIOUS INSTRUCTION = PP, X→PBR (0≤X≤7)
JMP X	JMP X	JUMP TO LOCATION X, X→LR (0≤X≤15) EXCEPT IF PREVIOUS INSTRUCTION = PP
JMS X	JMS X	JUMP TO SUBROUTINE AT X, LR + 1→L STACK, PR→P STACK, X→LR, 15→PR EXCEPT IF PREVIOUS INSTRUCTION = PP
RT	RT	L STACK→LR, P STACK→PR
RTS	RTS	L STACK→LR, P STACK→PR, SKIP INSTR.
NOP	NOP	NO OPERATION
	RTI	RETURN FROM INTERRUPT, RESTORE REGISTERS
	TLU	IF PREVIOUS INSTRUCTION WAS A PP, DO A TABLE LOOK-UP SEQUENCE: PC + 1→STACK RAM→PC(3 – 0), ACC→PC(7 – 4), PPR(3 – 2)→PC(9 – 8) ROM(7 – 4)→RAM, ROM(3 – 0)→ACC STACK→PC. IF PREVIOUS INSTRUCTION WAS NOT A PP, DO AN INDEXED SUBROUTINE CALL: PC + 1→STACK RAM→PC(3 – 0), ACC→PC(7 – 4)

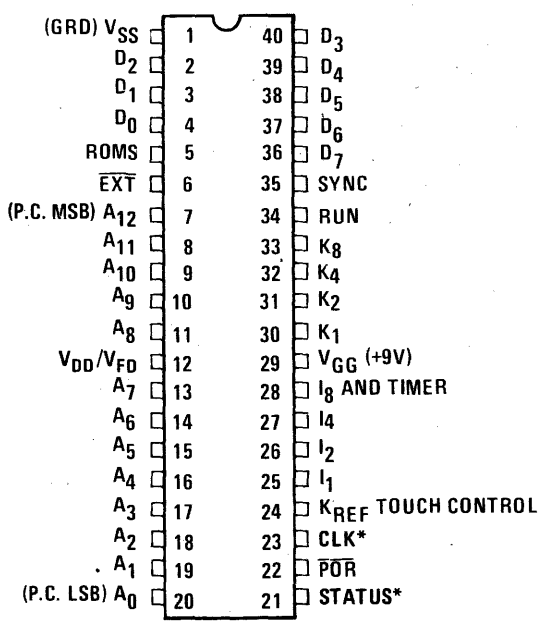
Skip Instructions (Skip 1 Non-PP Instruction) (RAM = Memory at BU,BL)

S2000/2150	S2200/2400	
SZC	SZC	SKIP IF CARRY = 0
SZM Z	SZM Z	SKIP IF RAM BIT Z = 0, 0≤Z≤3
SZK	SZK	SKIP IF K BIT(S) = 0, (BIT(S) IN LAST LAI)
SBE	SBE	SKIP IF BL = E
SAM	SAM	SKIP IF ACC = RAM
SZI		SKIP IF I BIT(S) = 0, (BIT(S) IN LAST LAI)
SOS		SKIP IF SF = 1, 0→SF. (SF = 'SECONDS' FLAG OUTPUT OF ÷50/÷60 COUNTER)
TF1		SKIP IF FLAG 1 = 1
TF2		SKIP IF FLAG 2 = 1
	SZMI Z +	SKIP IF RAM BIT = 0, (IN RAM BANK 1) 0≤Z≤255
	SKFL X +	SKIP IF FLAG = 1



Arithmetic and Logical Instructions

S2000/2150	S2200/2400	
ADCS	ADCS	RAM + ACC + CARRY→ACC + C, SKIP IF SUM≤15
ADIS X	ADIS X	X + ACC→ACC, SKIP IF SUM ≤15, CARRY UNALTERED
ADD	ADD	ACC + RAM→ACC, CARRY UNALTERED
AND	AND	ACC & RAM→ACC
XOR	XOR	ACC ⊕ RAM→ACC
STC	STC	1→CARRY
RSC	RSC	0→CARRY
CMA	CMA	15 – ACC→ACC (LOGICAL 1's COMPLEMENT ACC)
SF1		1→FLAG 1
RF1		0→FLAG 1
SF2		1→FLAG 2
RF2		0→FLAG 2
	SFLG X +	1→FLAG X
	RFLG X +	0→FLAG X



+ 8 bits in the second byte of an instruction.
*Assembled code contains complement of those arguments (assembler does it for you).

AMI S2000/2150 Detailed Block Diagram

S2000/S2150 Pin Configuration

*May be used for crystal input on S2150/2150A

Pin Descriptions — S2000/2150

PIN NO.	NAME	DESCRIPTION
1	V_{SS}	Most negative power-supply input. Typically grounded.
29	V_{GG}	Most positive power-supply input. Typically +9V.
12	V_{DD} (S2000) V_{FD} (S2000A)	Power supply input for all output buffers. Typically tied to V_{GG} or to a +5V supply. Power supply input for HV drive. Typically +32V
4 – 2, 40 – 36	D0 – D7	D Lines for input and output. Output during instructions OUT, DISN, DISB. Input during INP. Float at reset time or after an MVS instruction; or if RUN pin is low; or after a PSL with BL = 14. Display Latch outputs (DISN, DISB) can be inverted using EUR.
20 – 13 11 – 7	A0 – A12	A Lines for addressing and control. Changed by MVS as set up by PSH/PSL. When external program ROM is used, these lines output the contents of the Program Counter during the first half of each instruction cycle.
5	ROMS	ROM source control. Tied to a logic 1 or 0 to indicate internal ROM only, or internal plus external. Tied to SYNC to override Bank 0 with an external program, and to inverted SYNC to verify internal ROM contents.
6	$\overline{EXT}$	Active-low strobe output for D Lines. Generated by an OUT instruction during time T7.*
35	SYNC	Synchronization output for external devices or for external ROM control. Continuous square wave, low in T1 and T3, high in T5 and T7.* $f_{CLK} \div f_{SYNC} = 4$ for S2000, 8 for S2150.
34	RUN	Run/Wait control for prototyping and single-step testing. Logic 1 to run, logic 0 to wait with D Lines floating.
22	$\overline{POR}$	Power-On-Reset. Needs only an external capacitor, typically .05 microfarad. A pull-up to V_{GG} (15μA nominal) is provided internally.
23	CLK	On-chip oscillator connection. Runs at ~850kHz when connected to V_{SS} through 47pf and to V_{GG} through 30kΩ on the S2000. Crystal control possible; consult AMI.
21	STATUS	Monitors internal status for special designs. Logic 1 vs. logic 0 indicates: (during T1)* D Lines floating or not floating; (T3) BL equal or not equal to 13 for multiplex control; (T5) Carry is 1 or 0; (T7) Next instruction will or won't be skipped. On the S2150 a mask option allows use as a crystal oscillator pin.
24	KREF	K Lines voltage comparator reference input. Typically +3.0V, supplied by an external resistor divider.
30 – 33	K1, K2 K4, K8	K Lines, tested by SZK instruction. Any combination of these lines, selected by the last executed LAI instruction, are gated into the signal input of the voltage comparator. Unselected K Lines are discharged to V_{SS}, at 160μA typical.
25 – 28	I1, I2, I4, I8	I Lines, with internal pull-ups of 100μA nominal. Any combination of these lines, selected by the last executed LAI instruction (S2000, S2150), are gated into a common node tested by the SZI instruction. I8 also clocks a seconds timer whose output is tested using SOS.

*T1 is the first quarter-cycle following the falling edge of the SYNC output, T3 is the second, T5 is the third, and T7 is the fourth.

S2000/2150

Absolute Maximum Ratings (All voltages measured with respect to V_{SS})

Storage Temperature	−55°C to +125°C
Operating Temperature	0°C to +70°C
Operating Temperature (special request)	−40°C to +85°C
Maximum Positive Voltage	+18V
Maximum Negative Voltage	−0.3V
Maximum Output Currents	(See "Conditions" below)
I_{DD} Supply Current (depends on output loads)	+75mA
Total Average Power Dissipation	+700mW

S2000/2150

Electrical Characteristics

(V_{SS} = 0V, V_{GG} = +7.5V to +10.0V, V_{DD} = 5V*, T_A = 0°C to +70°C, f_{SYNC} = 125kHz to 225kHz)

	Parameter	Min.	Typ.	Max.	Units	Conditions
INPUTS	K_1 thru K_8					2.8 < K_{REF} < 3.2V
	Low Level	0		K_{REF} − 0.5	V	
	High Level	K_{REF} + 0.5		V_{GG}	V	
INPUTS	I_1 thru I_8, POR Schmitt-trigger					(Note 1)
	Low Level	0		1.7	V	
	High Level	5.3		V_{GG}	V	
INPUTS	ROMs, RUN					
	Low Level	0		0.8	V	
	High Level	3.5		V_{GG}		
INPUTS	D_0 thru D_7					
	Low Level	0		0.8	V	
	High Level − Program	5.0		V_{GG}	V	
	High Level − Data	3.5		V_{GG}	V	
OUTPUTS	A_0 thru A_3					
	High Level	3.5		*V_{DD}	V	I = −5mA**
	Low Level	0		0.8	V	I = +25mA**
OUTPUTS	A_4 thru A_{12} $\overline{EXT}$, SYNC, & S					
	High Level	3.5		*V_{DD}	V	I = −5mA**
	Low Level	0		0.6	V	I = +5mA**
OUTPUTS	D_0 thru D_7					
	High Level	3.5		*V_{DD}	V	I = −5mA**
	Low Level	0		1.0	V	I = +12mA**
I_{GG}	Supply Current		28	50	mA	
Δ RAM	RAM "Keep Alive"		20		μA/Bit	V_{RAM} = 4.0V
			30		μA/Bit	V_{RAM} = 9.0V

NOTE 1: There is an internal pull-up of 100μA nominal (15μA nominal on $\overline{POR}$) from each of these inputs to V_{GG}.

*V_{DD} may be connected to V_{GG} if single power supply operation is desired.

**At $V_{GG} \geq 8.5$VDC

Δ Available only on S2150/S2150A.

S2000A/S2150A

Preliminary Electrical Specifications

Absolute Maximum Ratings (All voltages measured with respect to V_{SS})

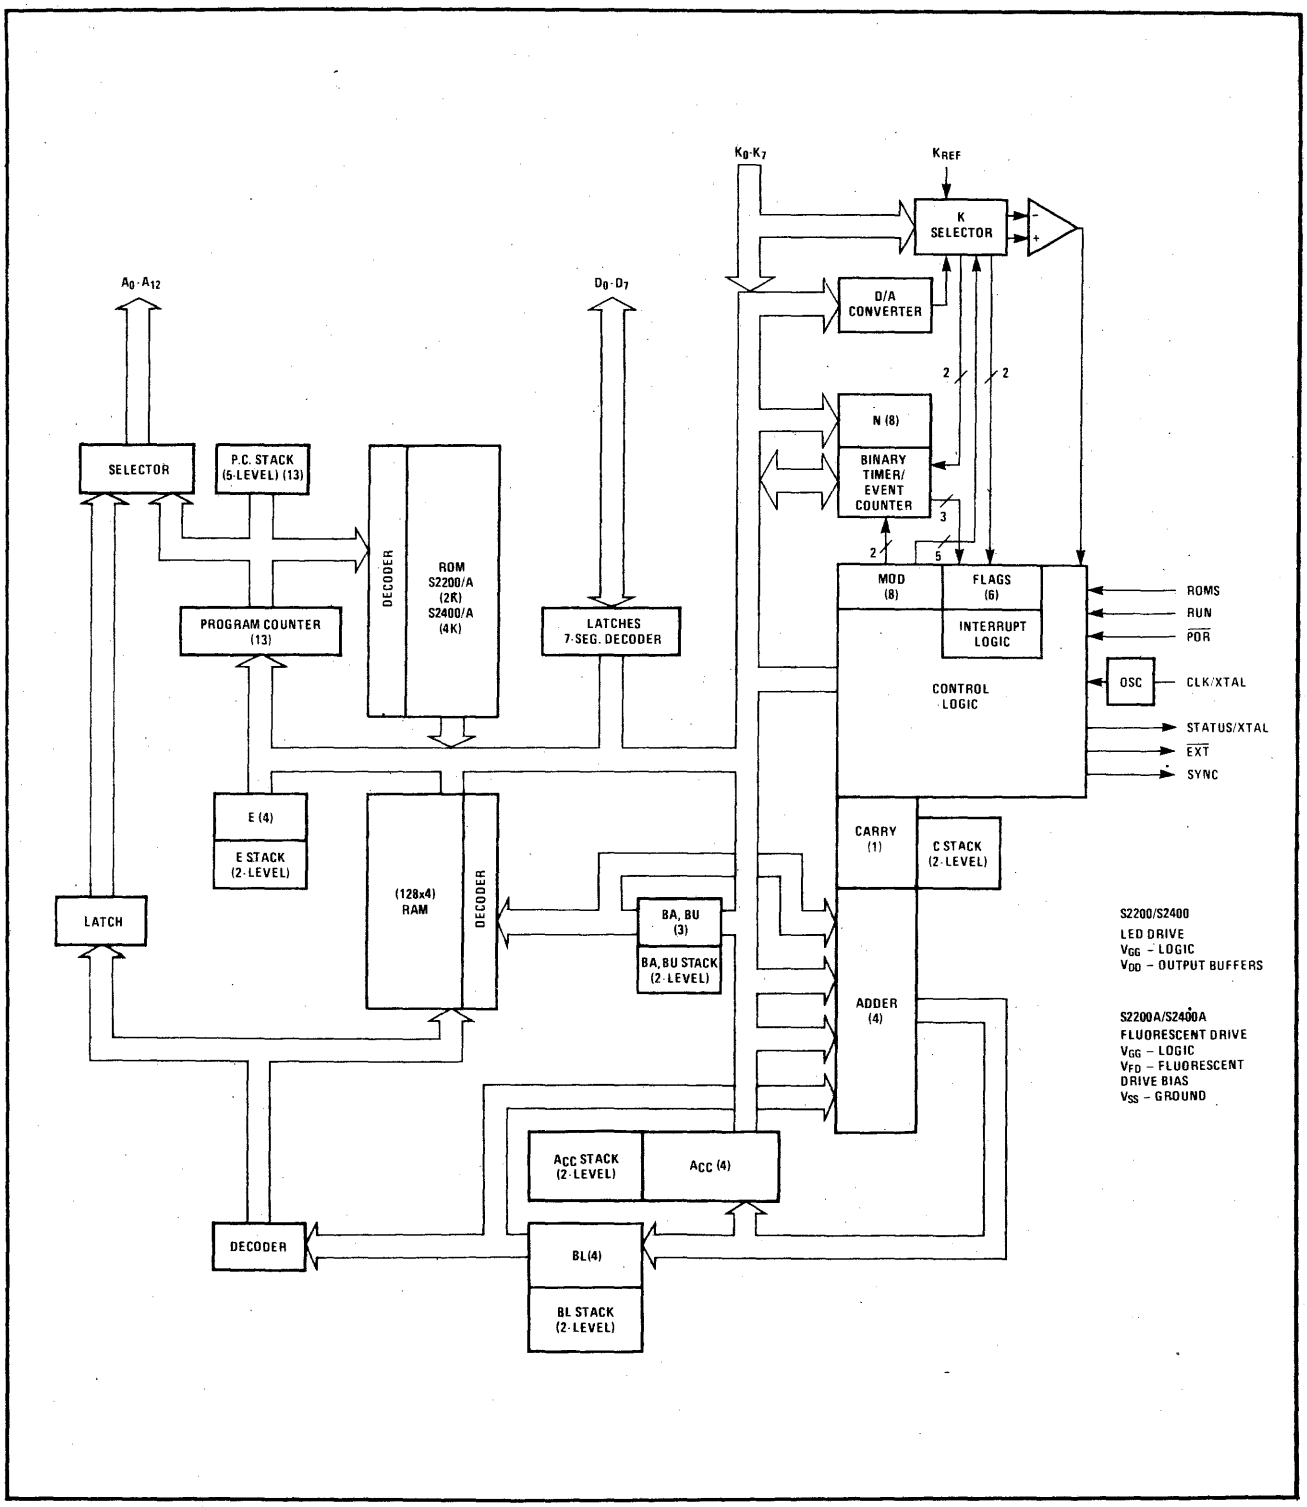
Storage Temperature	− 55°C to + 125°C
Operating Temperature	0°C to + 70°C
Operating Temperature (special request)	− 40°C to + 85°C
Maximum Positive Voltage, V_{FD}, A_0-A_4, D_0-D_7	+ 33V
All other pins	+ 18V
Maximum Negative Voltage, any pin	− 0.3V
Maximum Output Currents	(See Conditions below)
Source Current, any pin	− 10mA
Total Average Power Dissipation	+ 700mW
Rate of Rise of V_{FD}	1.6V/msec.
Maximum Voltage at V_{FD} with respect to V_{GG}	+ 22V

S2000A/S2150A

Electrical Characteristics — Specifications noted only for parameters which change from the S2000/2150 to the S2000A/2150A.

(V_{SS} = 0V, V_{GG} = 7.5 to 10.0V, V_{FD} = V_{GG} + 22V, T_A = 0°C to + 70°C. f_{SYNC} = 125kHz to 225kHz)

	Parameter	Min.	Typ.	Max.	Units	Conditions
OUTPUTS	D_0 thru D_7, A_0 thru A_4					
	High Level	− 3.5			mA	V_{OUT} = V_{FD} − 6V**
	Low Level			0.6	V	I = 250μA**
OUTPUTS	A_5 thru A_{12}, EXT, SYNC, & STATUS					
	High Level	3.5			V	I = − 5mA**
	Low Level			0.6	V	I = + 5mA**
I_{GG}	Supply Current		28	50	mA	No Loads



NOTE 1: The output buffers for lines A_5-A_{12} are supplied from V_{GG}.

NOTE 2: The high voltage parts, when biased with normal V_{FD}, are not TTL-compatible; when using external program ROM, it is necessary to interpose buffers.

NOTE 3: When applying power, V_{FD} must rise with or after V_{GG} at a rate not to exceed 1.6V/msec.

**At $V_{GG} \geq$ 8.5VDC

©IC MASTER 1979

S2200/2400 Block Diagram

For applications such as pulse width measurement, interval timing and event counting, the S2200/2400 has an 8-bit binary down-counter which counts 256 distinct states. The number of states (1 to 256) is controlled by the (Modulo-) N Register.

Another register, the MOD Register, controls the selection of inputs and outputs for the Programmable Counter/Timer, as well as the Display Latch output polarity and the voltage comparator's noninverting-input source.

S2200A Typical Microwave/Standard Oven Application

©IC MASTER 1979

S6800 Microcomputer Systems

The AMI S6800

The AMI S6800 Microprocessing Family hardware includes a microprocessor, ROM and RAM memories, and data input/output circuits. These components may be assembled in a building block manner into a very simple microcomputer system or into any of progressively more complex systems, which can be used in many general or special purpose applications. The important feature of the S6800 family is that within any system all components are directly compatible in signal functions, circuit performance characteristics, and logic levels. All operate on a single +5V power supply.

It remains to the user to integrate the microcomputer into his own large system and to program it for a specific task. The task may be either simple or complex and either general in purpose or highly specialized for one application.

To facilitate system design and programming, AMI will provide a comprehensive set of reference documents, design and programming aids, a program library, and other applications support. For example, AMI will make available a comprehensive hardware and software reference manual, a S6800 program assembler, and a simulator. Such design and programming support is a continuing and expanding effort at AMI.

S6800 — 8-Bit Microprocessor

The S6800/S68A00/S68B00 is an 8-bit parallel processor with the ability to address up to 65K bytes of memory and execute instructions in two microseconds. It is manufactured using N-channel MOS technology and operates on a single +5V power supply. All inputs and outputs are TTL compatible. The MPU has six internal registers, four types of vectored interrupts and 72 basic instructions. The basic instructions can be used in different addressing modes to save instruction execution time and memory space.

Another important advantage that the S6800/S68A00/S68B00 has to offer in comparison with any other microcomputer system is input/output versatility. In any computer system, large or small, the CPU internal functions are determined by its architecture and the user usually has little opportunity or need to alter them. On the other hand, the I/O configuration is almost always determined by the user and subject to change as peripherals are added or other system alternations are introduced.

S68A10/S68B10 — 1024 Bit (128x8) Static Read/Write Memory

The S68A10 and S68B10 are static Read/Write memories designed and organized to be compatible with the S68A00 and S68B00 microprocessors. Interfacing to the S68A10 and S68B10 consists of an 8-bit bi-directional data bus, seven address lines, a single Read/Write control line, and six chip enable lines, four negative and two positive.

For ease of use, the S68A10 and S68B10 are totally static memories requiring no clocks or cell refresh. The S68A10 and S68B10 are fabricated with N-channel silicon gate depletion load technology to be fully DTL/TTL compatible with only a single +5V power supply required. The data, address and control line organization and functions of the S68A10 and S68B10 match those of the MPU.

S68A21/S68B21 — Peripheral Interface Adapter (PIA)

The S68A21/S68B21 are peripheral interface adapters that provide the univeral means of interfacing peripheral equipment to the S68A00 and S68B00 Microprocessing Units (MPU). These devices are capable of interfacing the MPU to peripheral through two 8-bit bi-directional peripheral data buses and four control lines. No external logic is required for interfacing to most peripheral devices.

©IC MASTER 1979

The functional configuration of the PIA is programmed by the MPU during system initialization. Each of the peripheral data lines can be programmed to act as an input or output, and each of the four control/interrupt lines may be programmed for one of several control modes. This allows a high degree of flexibility in the overall operation of the interface.

The PIA interfaces to the S68A00/S68B00 MPUs with an 8-bit bi-directional data bus, three chip select lines, two register select lines, two interrupt request lines, read/write line, enable line and reset line. These signals in conjunction with the S68A00/S68B00 VMA output permit the MPU to have complete control over the PIA. VMA may be utilized to gate the input signals to the PIA.

S6831/A/B/C — 16,384 Bit (2048x8) Read Only Memory

The S6831/A/B/C is a 16,384-bit Read Only Memory organized 2K words by 8 bits. This ROM has been designed to supply large bit storage, high performance memory for microprocessors and other demanding applications with simple interface requirements. The device will operate from a single +5V power supply and is manufactured with N-channel silicon gate depletion load technology. This device is available in all common high-density ROM pinouts.

S6834 — 4096 Bit (512x8) Erasable and Electrically Reprogrammable ROM

The S6834 is a high-speed, static, 512x8 bit, erasable and electrically programmable read only memory designed for use in bus-organized systems. Both input and output are TTL compatible during both read and write modes. Packaged in a 24-pin hermetically sealed dual in-line package, the bit pattern can be erased by exposing the chip to an ultra-violet light source through the transparent lid, after which a new pattern can be written. The device has +5V and -12V power supplies and is processed using a mature P-channel process.

S68A50/S68B50 — Asynchronous Communication Interface Adapter (ACIA)

The S68A50/S68B50 Asynchronous Communication Adapter (ACIA) provides the data formatting and control to interface serial asynchronous data communications to bus organized systems such as the S68A00/S68B00 Microprocessing Units.

The S68A50/S68B50 includes select enable, read/write, interrupt and bus interface logic to allow data transfer over an 8-bit bi-directional data bus. The parallel data of the bus system is serially transmitted and received by the asynchronous data interface, with proper formatting and error checking. The functional configuration of the ACIA is programmed via the data bus during system initialization. Word lengths, clock division ratios and transmit control through the Request-to-Send output may be programmed. For modem operation three control lines are provided.

Basic S6800 Microcomputer System

In a basic system built with the S6800 components the S6800/S68A00/S68B00 Microprocessor is supported by over 1K bytes of memory and controls one input/output interface circuit. The 1024-byte ROM is used to store the operating program, the 128-byte RAM provides working storage for the MPU, and the Peripheral Interface Adapter (PIA) provides two independently programmable 8-bit input/output ports for communicating with two peripheral devices.

The S6800 system is bus oriented. Eight lines from the data bus and 16 more lines make up the address bus. The MPU controls the bus and all other devices — the memories and the PIA — attach to the busses and wait for instructions from the MPU to supply or receive data.

©IC MASTER 1979

The basic system is a complete microcomputer, which can be used for a large variety of applications. It is simple but versatile, because it can be easily reprogrammed by changing the ROM. The user must provide only the two-phase clock signal source, a power-up/restart circuit, and a single +5V power supply to complete the hardware.

Expanding the S6800 System

The basic system can be altered or expanded in many different ways. For example, the S68A50/S68B50 Asynchronous Communication Interface Adapter (ACIA) can be substituted for the PIA, to enable the microcomputer to interface with a telecommunications modem. Or, additional memory can be added — either RAM or ROM — to expand the processing capability of the MPU. In general, the system can be expanded in a modular manner, by adding onto the bus as many as ten devices out of the S6800 family. These can be any combination of memory or input/output interface circuits. In this manner a system of nearly any complexity and configuration can be assembled. (Systems with more than ten devices on the bus require the addition of address and data bus buffers to operate at full speed.)

By building a microcomputer from the S6800 family of devices, advantage is taken of the compatibility of the devices. They all conform to the bus discipline, all are compatible in load levels, and the entire system runs on a common system clock. In effect you eliminate most all circuit design, save for the simple clock and power-up/restart circuits. Because you are dealing with only a small number of integrated circuits, circuit layout is simple and the entire microcomputer can be located on a single circuit card.

In some special purpose applications you may need to attach your own interface devices to the bus. As a result, more circuit design will be required, but you will find the S6800 MPU easy to work with. It has features that allow it to be used in many different systems. For example, by using the Halt, Three-State Control, and Data Bus Enable lines, you can easily design a direct memory access system in which either the MPU or a peripheral device can read or write into the RAM and utilize the bus on a priority basis. You can also design a multiprocessor system in which several MPUs can be attached to the same bus and share processing assignments as well as memory space.

S6800 Input/Output

One of the most important advantages that any S6800 system has to offer is its input/output versatility.

In a S6800 system the MPU relegates most of the I/O control to such I/O interfaces as the PIA or ACIA. Each of these circuits is programmable and can interface with peripheral devices without directly involving the MPU. For example, the MPU can preprogram a PIA to either output data to the MPU or to receive it. Thereafter, the PIA circuits assume all functions of interfacing with the peripherals and the MPU never has to look at the interface until service is required. It must service interrupts from the PIA, but never needs to wait for input data to become available or for output data to be accepted. This relieves the MPU of its I/O functions, makes it more efficient in its primary task of data processing, and significantly increases system throughput.

The I/O interfaces and memory are both located in the same address space with the S6800 system. The MPU can access any I/O device the same as a memory location — with address lines, instead of separate I/O control lines. Therefore, it can manipulate data in the I/O interface registers with the same programmed instructions as it uses for memory locations. This adds flexibility and increases system efficiency.

©IC MASTER 1979

The S6800 Instruction Set complements the above I/O addressing capability with specific instructions that can be used to access memory as well as I/O circuit registers and perform directly various manipulations on the data.

S6800 Instruction Set

The S6800 MPU has a set of 72 basic instructions. These include binary and decimal arithmetic functions as well as logical, shift, rotate, load, store, branch, interrupt, and stack manipulation functions. Most of the instructions have several variations and most can be used with several memory addressing modes. The total complex of instructions available to the programmer is actually 197.

An instruction can be from one to three bytes long, depending on the addressing mode used with the instruction. The first byte always contains the operation code, which designates the kind of operation the MPU will perform. In single byte instructions no memory address is required, because the operation is performed on one of the internal MPU registers. In multiple byte instructions the second and third byte can be the operand, or a memory address for the operand.

A noteworthy feature of the S6800 MPU is that some of the instructions can operate directly on any memory location. In other computer systems it is common that the processor fetches an operand from memory, stores it in the accumulator, then executes the operation in the ALU and finally writes the result back into the memory. The S6800 is able to accomplish the same with only a single instruction, because it operates with any external location in the same manner as with an internal register. For example, it can directly increment or decrement the contents of a memory location. Because the MPU addresses I/O devices just like a memory location, it can do the same with registers inside the PIA or ACIA. The ASL, ASR, LSR, and ROL are other examples of instructions which operate in this manner.

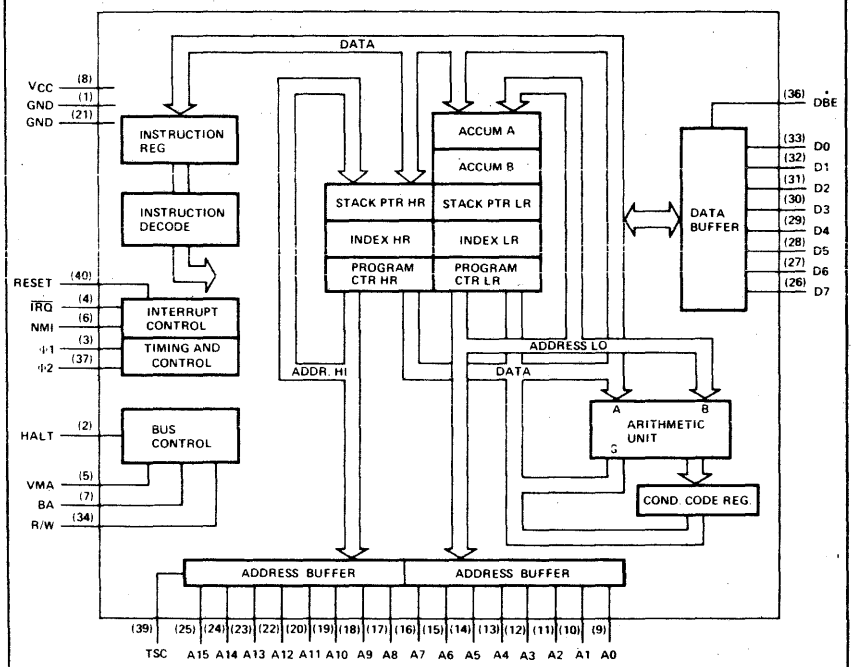
MPU Registers

Accumulators A and B — Two separate 8-bit accumulators that are used to hold operands and results of operations in the ALU.

Index Register — A 16-bit register used for memory address storage in Indexed Addressing operations.

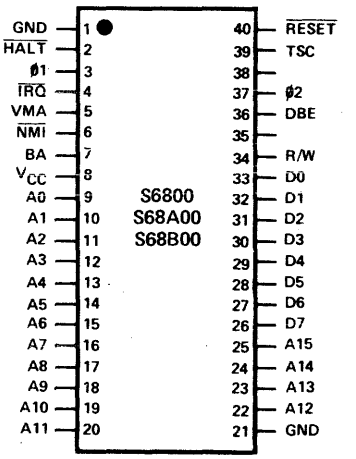
Program Counter — A 16-bit register that holds the current program instruction address. Once the initial program starting address is loaded into the program counter, it is incremented under control of the MPU hardware.

Stack Pointer — A 16-bit register used for storage of the next available location in an external push-down/pop-up stack.



Condition Code Register — An 8-bit register that stores certain results of operations in the ALU. These bits are used as testable conditions for the conditional branch instructions. In addition, one bit position stores the interrupt mask bit and the two high order bits are unused.

Memory Register



External Stack — The MPU uses a push-down/pop-up stack that can be located anywhere in RAM and be of any convenient size. It is accessed with the stack pointer address and has several uses. First, it always stores the MPU register contents following an interrupt and return addresses during subroutine execution. Second, it can also be used by the programmer to store data during program execution.

8-BIT
MICROPROCESSOR

BLOCK DIAGRAM

PIN CONFIGURATION

FEATURES

- Eight-Bit Parallel Processing
- Bi-Directional Data Bus
- Sixteen-Bit Address Bus – 65536 Bytes of Addressing
- 72 Instructions – Variable Length
- Seven Addressing Modes – Direct, Relative, Immediate, Indexed, Extended, Implied and Accumulator
- Variable Length Stack
- Vectored Restart
- 2 Microsecond Instruction Execution
- Maskable Interrupt Vector
- Separate Non-Maskable Interrupt – Internal Registers Saved in Stack
- Six Internal Registers – Two Accumulators, Index Register, Program Counter, Stack Pointer and Condition Code Register
- Direct Memory Access (DMA) and Multiple Processor Capability
- Clock Rates – S6800 – 1.0 MHz
  S68A00 – 1.5 MHz
  S68B00 – 2.0 MHz
- Simple Bus Interface Without TTL
- Halt and Single Instruction Execution Capability

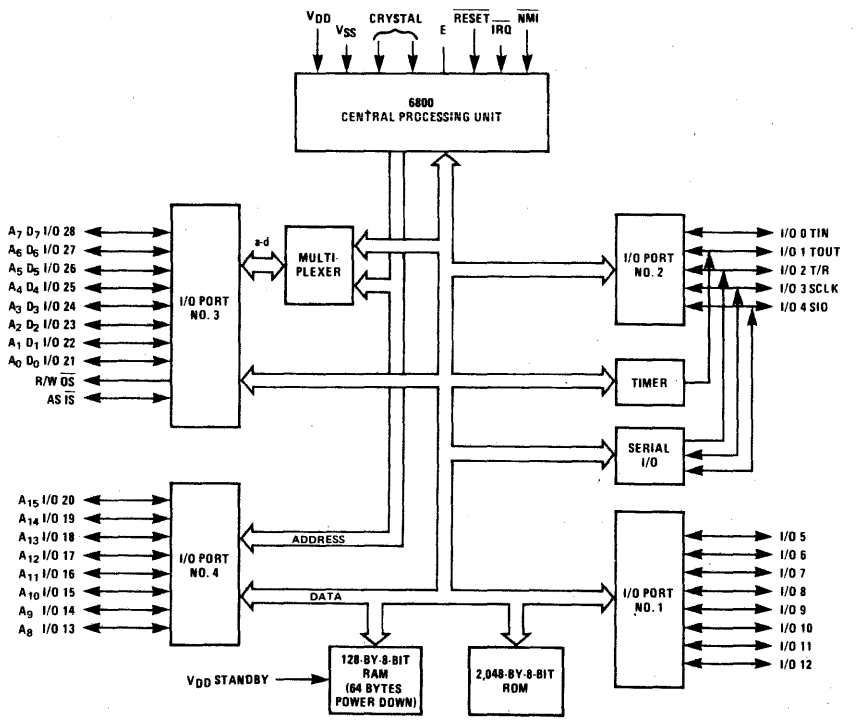
MICROCOMPUTER UNIT (MCU)*

Features



- Expanded S6800 instruction set
- Object code compatible with S6800
- Single chip or expandable to 65K words.
- 2K bytes of ROM
- 128 bytes of RAM (64 bytes retainable)
- 31 parallel I/O lines
- Internal Clock/Divide-by-Four mask option (S6801)
- External Clock/Divide-by-One mask option (S6801E)
- TTL compatible inputs and outputs
- Interrupt capability
- Hardware Multiply

General Description

The S6801 MCU is an 8-bit microcomputer system which is expandable, using the S6800 microprocessor family. The S6801 MCU is object code compatible with the S6800 instruction set with improved execution times of key instructions plus several new 16-bit and 8-bit instructions. The S6801 MCU can operate single chip or be expanded to 65K words. The S6801 MCU is TTL compatible and requires one + 5.0 volt power supply. The S6801 MCU has 2K bytes of ROM and 128 bytes of RAM on board. In addition, the S6801 MCU has on board serial and parallel I/O and three 16 stage timer function.

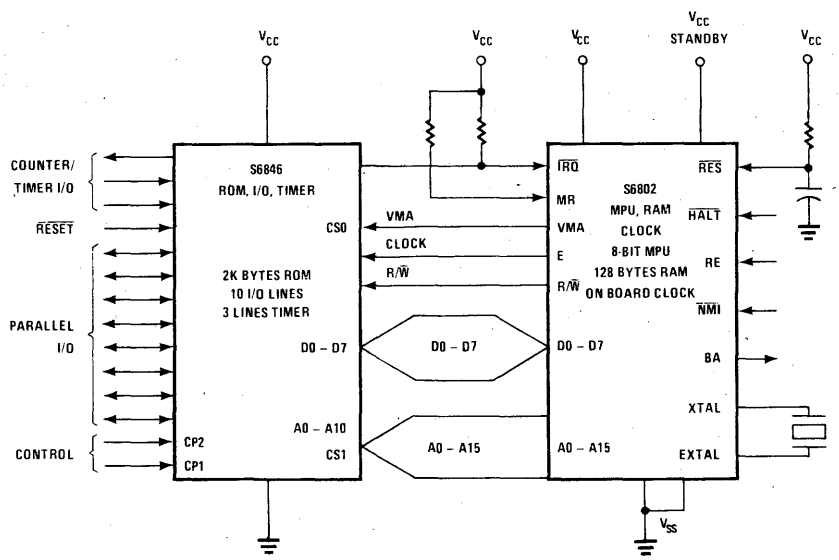
MICROPROCESSOR WITH CLOCK AND RAM

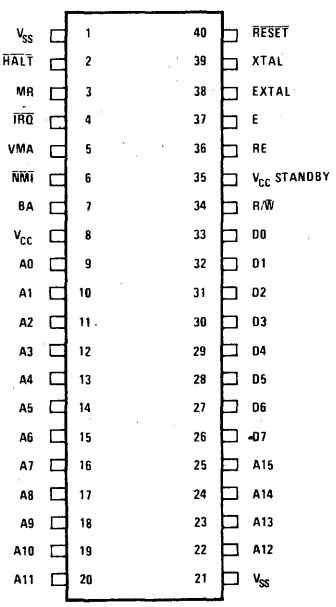
Features



- ☐ On-Chip Clock Circuit
- ☐ 128 x 8 Bit On-Chip RAM
- ☐ 32 Bytes of RAM Are Retainable
- ☐ Software-Compatible with the S6800
- ☐ Expandable to 65K Words
- ☐ Standard TTL-Compatible Inputs and Outputs
- ☐ 8-Bit Word Size
- ☐ 16-Bit Memory Addressing
- ☐ Interrupt Capability

General Description

The S6802 is a monolithic 8-bit microprocessor that contains all the registers and accumulators of the present S6800 plus an internal clock oscillator and driver on the same chip. In addition, the S6802 has 128 bytes of RAM on board located at hex addresses 0000 to 007F. The first 32 bytes of RAM, at hex addresses 0000 to 001F, may be retained in a low power mode by utilizing V_{CC} standby, thus facilitating memory retention during a power-down situation.



The S6802 is completely software compatible with the S6800 as well as the entire S6800 family of parts. Hence, the S6802 is expandable to 65K words. When the S6802 is interfaced with the S6846 ROM — I/O — Timer chip, as shown in the Block Diagram below, a basic 2-chip microcomputer system is realized.

Typical Microcomputer Block Diagram

BLOCK DIAGRAM OF A TYPICAL COST EFFECTIVE MICROCOMPUTER. THE MPU IS THE CENTER OF THE MICROCOMPUTER SYSTEM AND IS SHOWN IN A MINIMUM SYSTEM INTERFACING WITH A ROM COMBINATION CHIP. IT IS NOT INTENDED THAT THIS SYSTEM BE LIMITED TO THIS FUNCTION BUT THAT IT BE EXPANDABLE WITH OTHER PARTS IN THE S6800 MICROCOMPUTER FAMILY.

HIGH PERFORMANCE MICROPROCESSOR*

Features

- Upward source compatible with S6800
- Bus compatible with S6800 family
- 2MHz Bus operation
- Pin-out compatible with S6800/S6802
- On-chip Oscillation/Clock Driver
- TTL compatible I/O
- 3 priority Interrupts
- Fast Interrupt — Cuts Response Time
- Interrupt acknowledge allows vectoring by device
- Memory Ready Signal for slow memory
- +5V Power Supply
- Expandable to 64 K words

Block Diagram

General Description

The S6809 is a monolithic microprocessor that contains all the registers of the S6800 plus an additional clock oscillator and driver on chip.

The S6809 gives the user 8- and 16-bit word capability, while retaining software compatibility with the basic S6800 family. Four 8-bit-wide registers and five 16-bit-wide ones process the data, with the 8-bit accumulators supplying routing computation.

The S6809 is compatible with the complete set of S6800 peripheral and memory devices. It is designed for the middle and high end of the microprocessor scale.

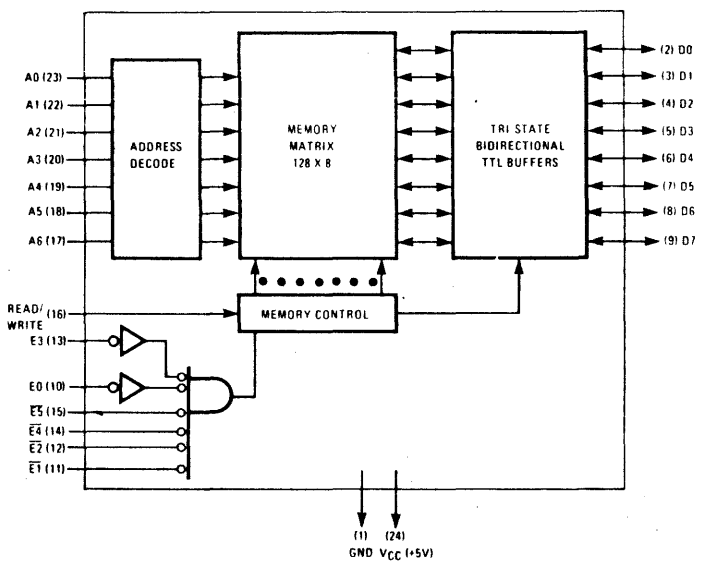
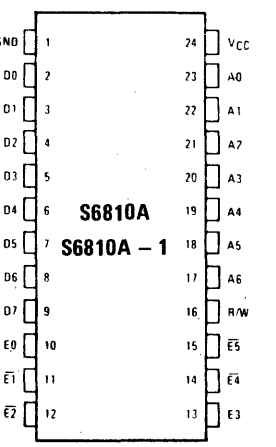
128x8 STATIC READ/WRITE MEMORY

Features



- ☐ Organized as 128 Bytes of 8 Bits
- ☐ Static Operation
- ☐ Bi-Directional Three-State Data Input/Output
- ☐ Six Chip Enable Inputs (Four Active Low, Two Active High)
- ☐ Single 5-Volt Power Supply
- ☐ TTL Compatible
- ☐ Maximum Access Time = 450ns for S6810A 350ns for S6810A – 1

General Description



The S6810A is a static 128 x 8 Read/Write Memory designed and organized to be compatible with the S6800 Microprocessor. Interfacing to the S6810A consists of an 8-Bit Bidirectional Data Bus, Seven Address Lines, a single Read/Write Control line, and six Chip Enable lines – four negative and two positive.

For ease of use, the S6810A is a totally static memory requiring no clocks or cell refresh. The S6810A is fabricated with N-channel silicon gate depletion mode technology to be fully DTL/TTL compatible with only a single +5 volt power supply required.

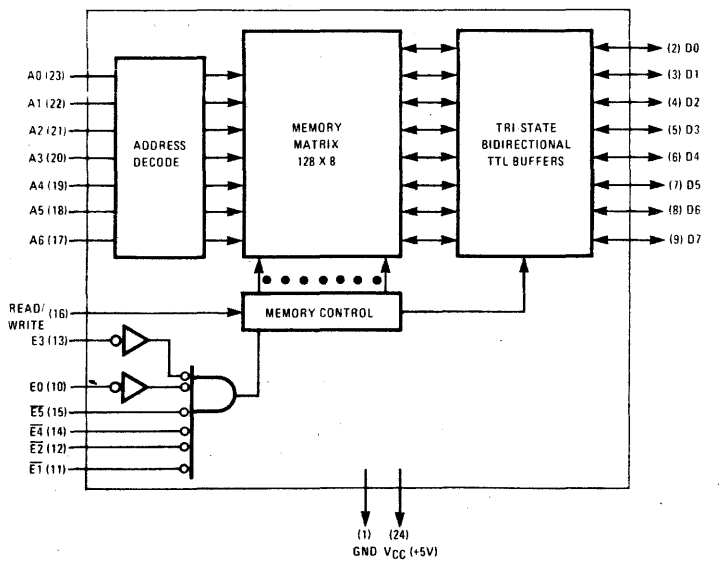
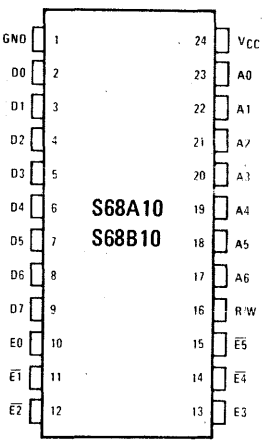
128 × 8 STATIC READ/WRITE MEMORY

Features



- Organized as 128 Bytes of 8 Bits
- Static Operation
- Bidirectional Three-State Data Input/Output
- Six Chip Enable Inputs (Four Active Low, Two Active High)
- Single 5 Volt Power Supply
- TTL Compatible
- Maximum Access Time:
  —360ns for S68A10
  —250ns for S68B10

General Description



The S68A10 and S68B10 are static 128x8 Read/Write Memories designed and organized to be compatible with the S68A00 and S68B00 Microprocessors. Interfacing to the S68A10 and S68B10 consists of an 8-bit bidirectional data bus, seven address lines, a single Read/Write control line, and six chip enable lines, four negative and two positive.

For ease of use, the S68A10 and S68B10 are a totally static memory requiring no clocks or cell refresh. The S68A10 and S68B10 are fabricated with N-channel silicon gate depletion load technology to be fully DTL/TTL compatible with only a single +5 volt power supply required.

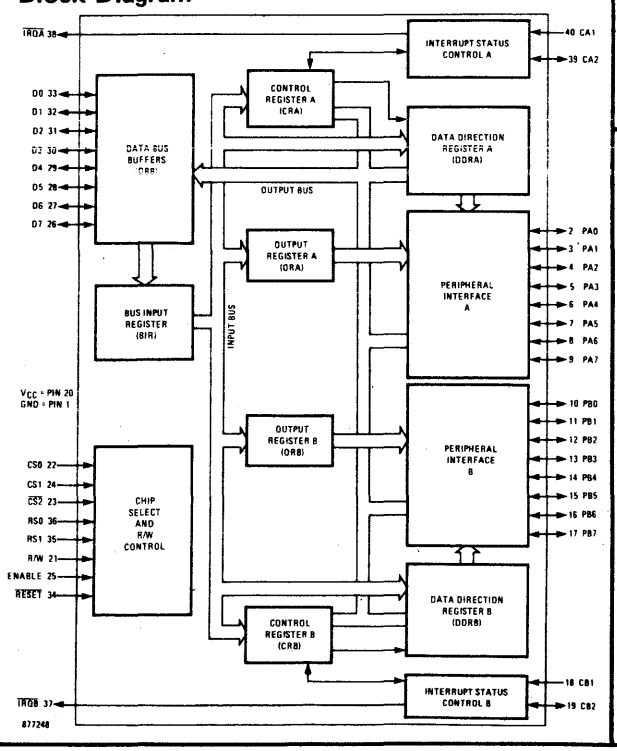
Peripheral Interface Adapter (PIA)

Features

- 8-Bit Bidirectional Data Bus for Communication with the MPU
- Two Bidirectional 8-Bit Buses for Interface to Peripherals
- Two Programmable Control Registers
- Two Programmable Data Direction Registers
- Four Individually-Controlled Interrupt Input Lines: Two Usable as Peripheral Control Outputs
- Handshake Control Logic for Input and Output Peripheral Operation
- High-Impedance Three-State and Direct Transistor Drive Peripheral Lines
- Program Controlled Interrupt and Interrupt Disable Capability
- CMOS Compatible Peripheral Lines



General Description

The S68A21/S68B21 are peripheral Interface Adapters that provide the universal means of interfacing peripheral equipment to the S68A00 and the S68B00 Microprocessing Units (MPU). This device is capable of interfacing the MPU to peripherals through two 8-bit bidirectional peripheral data buses and four control lines. No external logic is required for interfacing to most peripheral devices.

The functional configuration of the PIA is programmed by the MPU during system initialization. Each of the peripheral data lines can be programmed to act as an input or output, and each of the four control/interrupt lines may be programmed for one of several control modes. This allows a high degree of flexibility in the overall operation of the interface.

The PIA interfaces to the S68A00/S68B00 MPUs with an eight-bit bidirectional data bus, three chip select lines, two register select lines, two interrupt request lines, read/write line, enable line and reset line. These signals, in conjunction with the S68A00/S68B00 VMA output, permit the MPU to have complete control over the PIA. VMA may be utilized to gate the input signals to the PIA.

Application Information

Initialization

A low reset line has the effect of zeroing all PIA registers. This will set PA0-PA7, PB0-PB7, CA2 and CB2 as inputs, and all interrupts disabled. The PIA must be configured during the restart program which follows the reset.

Register Addressing

There are six locations within the PIA accessible to the MPU data bus: two Peripheral Registers, two Data Direction Registers, and two Control Registers. Selection of these locations is controlled by the RS0 and RS1 inputs together with bit 2 in the Control Register, as shown in Table 1.

Table 1. Internal Addressing

RS1	RS0	Control Register Bit CRA-2	Control Register Bit CRB-2	Location Selected
0	0	1	X	Peripheral Register A
0	0	0	X	Data Direction Register A
0	1	X	X	Control Register A
1	0	X	1	Peripheral Register B
1	0	X	0	Data Direction Register B
1	1	X	X	Control Register B

X = Don't Care

Data Direction Registers (DDRA and DDRB)

The two Data Direction Registers allow the MPU to control the direction of data through each corresponding peripheral data line. All Data Direction Register bits set at "0" configure the corresponding peripheral data line as an input; all "1's" result in an output.

Control Registers (CRA and CRB)

The two Control Registers (CRA and CRB) allow the MPU to control the operation of the four peripheral control lines, CA1, CA2, CB1 and CB2. In addition, they allow the MPU to enable the interrupt lines and monitor the status of the interrupt flags. Bits 0 through 5 of the two registers may be written or read by the MPU when the proper chip select and register select signals are applied. Bits 6 and 7 of the two registers are read only and are modified by external interrupts occurring on control lines CA1, CA2, CB1 or CB2. The format of the control words is shown in Table 2.

Table 2. Control Word Format

	7	6	5	4	3	2	1	0
CRA	IRQA1	IRQA2	CA2 Control			DDRA Access	CA1 Control	
CRB	IRQB1	IRQB2	CB2 Control			DDRB Access	CB1 Control	

Data Direction Access Control Bit (CRA-2 and CRB-2) — Bit 2 in each Control Register (CRA and CRB) allows selection of either a Peripheral Interface Register or the Data Direction Register when the proper register select signals are applied to RS0 and RS1.

Control of CA1 and CB1 Interrupt Input Lines (CRA-0, CRB-0, CRA-1 and CRB-1) — The two lowest order bits of the control registers are used to control the interrupt input lines CA1 and CB1. Bits CRA-0 and CRB-0 are used to enable the MPU interrupt signals $\overline{IRQA}$ and $\overline{IRQB}$, respectively. Bits CRA-1 and CRB-1 determine the active transition of the interrupt input signals CA1 and CB1 (Table 3).

Control of CA2 and CB2 Peripheral Control Lines (CRA-3, CRA-4, CRA-5, CRB-3, CRB-4 and CRB-5) — Bits 3, 4 and 5 of the two control registers are used to control the CA2 and CB2 Peripheral Control lines. These bits determine if the control lines will be an interrupt input or an output control signal. If bit CRA-5 (CBR-5) is low, CA2 (CB2) is an interrupt input line similar to CA1 (CB1) (Table 4). When CRA-5 (CRB-5) is high, CA2 (CB2) becomes an output signal that may be used to control peripheral data transfers. When in the output mode, CA2 and CB2 have slightly different characteristics (Tables 5 and 6).

Interrupt Flags (CRA-6, CRA-7, CRB-6 and CRB-7) — The four interrupt flag bits are set by active transitions of signals on the four Interrupt and Peripheral Status lines when those lines are programmed to be interrupt inputs. These bits cannot be set directly from the MPU Data Bus and are reset indirectly by a Read Peripheral Data Operation on the appropriate section.

©IC MASTER 1979

Table 3. Control of Interrupt Inputs CA1 and CB1

CRA-1 (CRB-1)	CRA-0 (CRB-0)	Interrupt Input CA1 (CB1)	Interrupt Flag CRA-7 (CRB-7)	MPU Interrupt Request $\overline{IRQA}$ ($\overline{IRQB}$)
0	0	↓ Active	Set high on ↓ of CA1 (CB1)	Disabled — $\overline{IRQ}$ remains high
0	1	↓ Active	Set high on ↓ of CA1 (CB1)	Goes low when the interrupt flag bit CRA-7 (CRB-7) goes high
1	0	↑ Active	Set high on ↑ of CA1 (CB1)	Disabled — $\overline{IRQ}$ remains high
1	1	↑ Active	Set high on ↑ of CA1 (CB1)	Goes low when the interrupt flag bit CRA-7 (CRB-7) goes high

Notes:
1. ↑ indicates positive transition (low to high).
2. ↓ indicates negative transition (high to low).
3. The Interrupt flag bit CRA-7 is cleared by an MPU Read of the A Data Register, and CRB-7 is cleared by an MPU Read of the B Data Register.
4. If CRA-0 (CRB-0) is low when an interrupt occurs (Interrupt disabled) and is later brought high, $\overline{IRQA}$ ($\overline{IRQB}$) occurs on the positive transition of CRA-0 (CRB-0).

Table 4. Control of CA2 and CB2 as Interrupt Inputs CRA-5 (CRB-5) is Low

CRA-5 (CRB-5)	CRA-4 (CRB-4)	CRA-3 (CRB-3)	Interrupt Input CA2 (CB2)	Interrupt Flag CRA-6 (CRB-6)	MPU Interrupt Request $\overline{IRQA}$ ($\overline{IRQB}$)
0	0	0	↓ Active	Set high on ↓ of CA2 (CB2)	Disabled — $\overline{IRQ}$ remains high
0	0	1	↓ Active	Set high on ↓ of CA2 (CB2)	Goes low when the interrupt flag bit CRA-6 (CRB-6) goes high
0	1	0	↑ Active	Set high on ↑ of CA2 (CB2)	Disabled — $\overline{IRQ}$ remains high
0	1	1	↑ Active	Set high on ↑ of CA2 (CB2)	Goes low when the interrupt flag bit CRA-6 (CRB-6) goes high

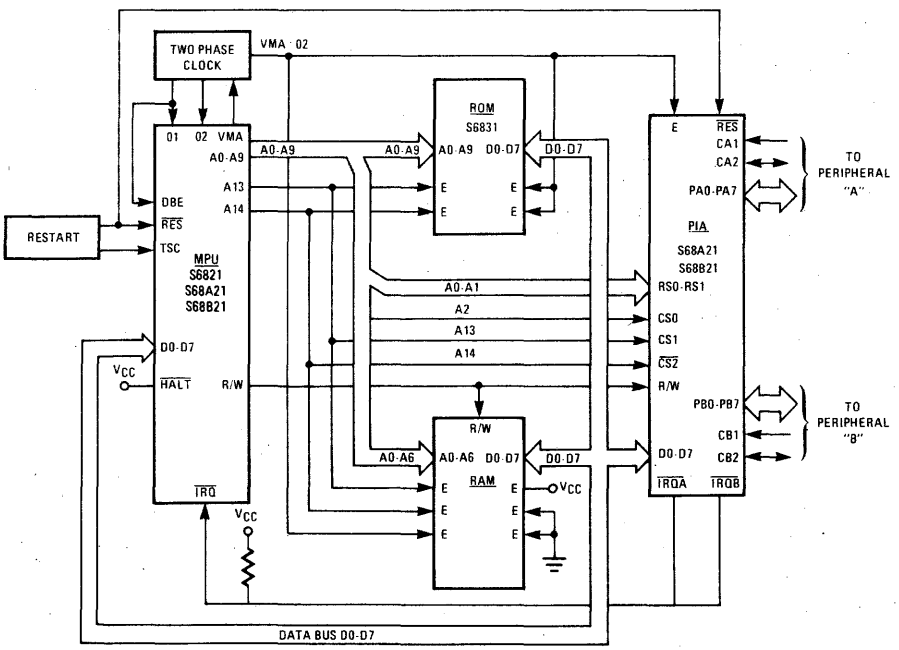
Notes:
1. ↑ indicates positive transition (low to high).
2. ↓ indicates negative transition (high to low).
3. The Interrupt flag bit CRA-6 is cleared by an MPU Read of the A Data Register and CRB-6 is cleared by an MPU Read of the B Data Register.
4. If CRA-3 (CRB-3) is low when an interrupt occurs (Interrupt disabled) and is later brought high, $\overline{IRQA}$ ($\overline{IRQB}$) occurs on the positive transition of CRA-3 (CRB-3).

©IC MASTER 1979

Basic System Configuration

The Microprocessing Unit (MPU) may be configured with a Read Only Memory (ROM), Random Access Memory (RAM), a Peripheral Interface Adapter (PIA), restart circuitry and clock circuitry to form a minimum functional system (Figure 16). Such a system can easily be adapted for a number of small scale applications by simply changing the content of the ROM.

Two-Phase Clock Circuitry and Timing — The MPU requires a two-phase non-overlapping clock which has a frequency range as high as 1MHz. In addition to the two phases, this circuit should also generate an enable Signal E, and its complement E, to enable ROMs, RAMs, PIAs and ACIAs. This Enable signal and its complement are obtained by ANDing $\phi 2$ and VMA (Valid Memory Address).



Chip Selection and Addressing — The minimum system configuration permits direct selection of the ROM, RAM, ACIA and PIA without the use of special TTL select logic. This is accomplished by simply wiring the address lines A13, A14 to the Enable or chip select lines on the memories and PIA. This permits the devices to be addressed as follows:

Device	A14	A13	Hex Addresses
RAM	0	0	0000-007F
PIA	0	1	2004-2007 (Registers)
ROM	1	1	6000-63FF

Other addressing schemes can be utilized which use any combination of two of the lines A10 through A14 for chip selection.

Peripheral Control — All control and timing for the peripherals that are connected to the PIA is accomplished by software routines under the control of the MPU.

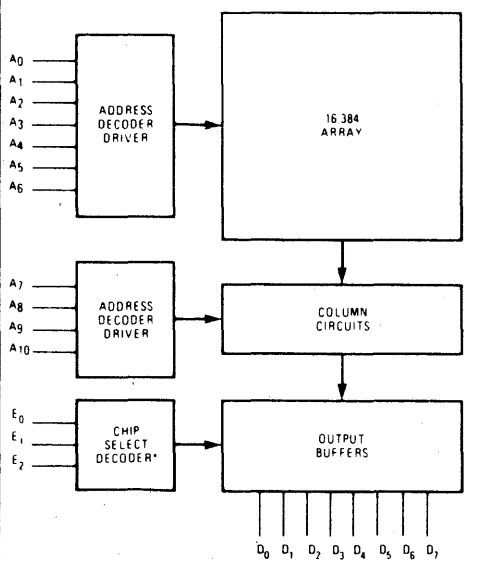
16,384 BIT (2048x8) STATIC NMOS ROM

Features

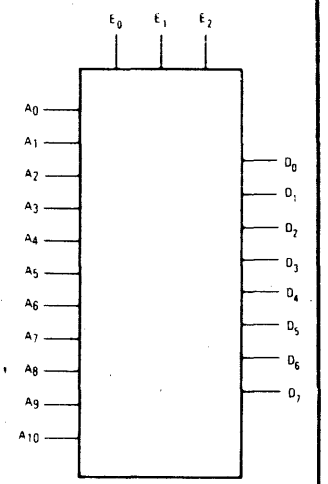
- ☐ Single +5V Power Supply
- ☐ Directly TTL Compatible Inputs
- ☐ Three-State TTL Compatible Outputs
- ☐ Three Programmable Enables
- ☐ Access Time: 450ns Maximum
- ☐ S6831A: Intel 2316A Pin Compatible
- ☐ S6831B: 2716 EPROM Pin Compatible
- ☐ Low Power: Supply Current is 80mA Maximum



General Description

The AMI 6831 family of 16,384 bit mask programmable Read-Only-Memories offers fully static operation with a single + 5V power supply. The device is fully TTL compatible on all inputs and three-state outputs. The three enables are mask programmable, the active level is specified by the user.

The S6831 family is available in two pin configurations. One of these, the S6813A, is the pin configuration of a popular ROM: the Intel 2316A. The second pin configuration, the S6813B, is pin compatible with the 2708 and 2716 EPROMs. Software developed in EPROMs can be put in low cost ROM for high volume production.



The device is organized as 2048 words by 8 bits, a configuration particularly suitable for microprocessors. The S6831 family is manufactured with an N-channel silicon gate depletion load technology.

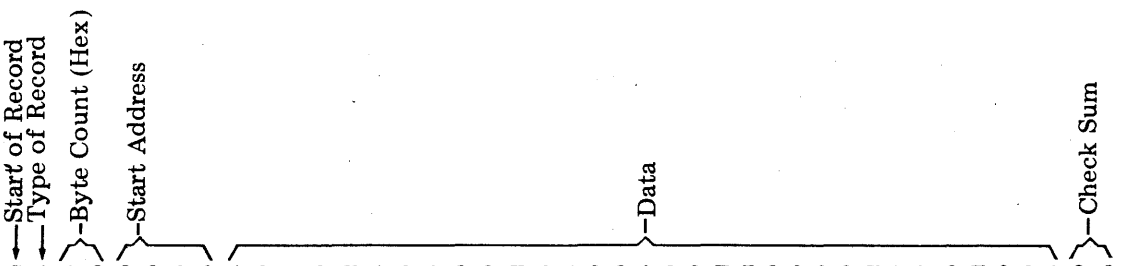
A.C. Test Conditions

Output Load	1 TTL Gate and C_L = 100 pF
Input Pulse Levels	0.8 to 2.4V
Input Rise and Fall Times (10% to 90%)	20 ns

Timing Measurement Reference Level

Input	1V and 2.2V
Output	0.8V and 2.0V



Custom Programming

The preferred method of pattern submission is the AMI Hex format as described below, with its built-in address space mapping and error checking. This is the format produced by the AMI Assembler. The format is as follows and may be on paper tape, punched cards or other media readable by AMI.

Position	Description
1	**Start of record (Letter S)**
2	**Type of record** 0 — Header record (comments) 1 — Data record 9 — End of file record
3, 4	**Byte Count** Since each data byte is represented as two hex characters, the byte count must be multiplied by two to get the number of characters to the end of the record. (This includes checksum and address data.) Records may be of any length defined in each record by the byte count.
5, 6, 7, 8	**Address Value** The memory location where the first data byte of this record is to be stored. Addresses should be in ascending order.
9, . . ., N	**Data** Each data byte is represented by two hex characters. Most significant character first.
N+1, N+2	**Checksum** The one's complement of the additive summation (without carry) of the data bytes, the address, and the byte count.

Example:

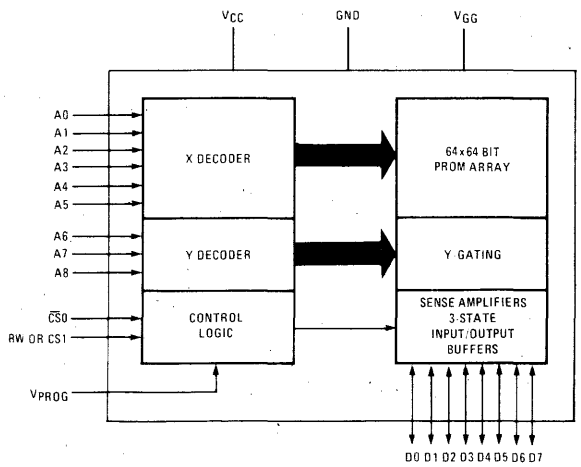
```
S 1 1 3 0 0 0 0 4 9 E 9 F 1 0 3 2 0 F 0 4 9 3 1 3 9 F 7 2 0 0 0 F 5 E 0 F 0 0 1 2 6
S 9 0 3 0 0 0 0 F C
```

NOTES:

1. Only positive logic formats for E_0, E_1, E_2 are accepted. 1 = V_{HIGH}; 0 = V_{LOW}
2. A "0" indicates the chip is enabled by a logic 0.
   A "1" indicates the chip is enabled by a logic 1.
3. Paper tape format is the same as the card format above except:
   a. The record should be a maximum of 80 characters.
   b. Carriage return and line feed after each record followed by another record.
   c. There should NOT be any extra line feed between records at all.
   d. After the last record, four (4) $$$$ (dollar) signs should be punched with carriage return and line feed indicating end of file.

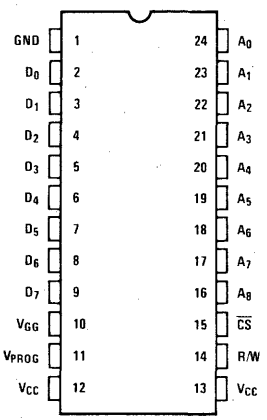
©IC MASTER 1979

ERASABLE AND ELECTRICALLY REPROGRAMMABLE READ ONLY MEMORY



Features

- ☐ On-Board Programmability
- ☐ Fast Access Time — 575ns Typ.
- ☐ Pin Configuration Similar to the S6830 1K x 8 Bit ROM
- ☐ High Speed Programming — Less than 1 Minute for All 4096 Bits
- ☐ Programmed with R/W, CS and V_{PROG} Pins
- ☐ Completely TTL Compatible — Excluding the V_{PROG} Pin
- ☐ Ultraviolet Light Erasable — Less than 10 Minutes
- ☐ Static Operation — No Clocks Required
- ☐ Three-State Data I/O
- ☐ Standard Power Supplies +5V and −12V
- ☐ Mature P-Channel Process



General Description

The S6834 is a high speed, static, 512 x 8 bit, erasable and electrically programmable read only memory designed for use in bus-organized systems. Both input and output are TTL compatible during both read and write modes. Packaged in a 24 pin hermetically sealed dual in-line package the bit pattern can be erased by exposing the chip to an ultra-violet light source through the transparent lid, after which a new pattern can be written.

Block Diagram

Pin Configuration

Typical Applications

- ☐ ROM Program Debugging
- ☐ Code Translation
- ☐ Microprogramming
- ☐ Look-up Tables
- ☐ Random Logic Replacement
- ☐ Programmable Waveforms
- ☐ Character Generation
- ☐ Electronic Keyboards

CONTROL FUNCTION TRUTH TABLE

CS	R/W	V_{PROG}	MODE	OUTPUTS
0	0	V_{PROG}	Write	Active Data Inputs
0	1	V_{CC}	Read	Active
1	X	X	Standby	Floating

OPERATION

Initially, and after each erasure, all bits of the 6834 are in the logic "0" state (output 0 volts). Data is stored by selectively programming a logic "1" into the desired bit locations. The R/W input (pin 14) is used to select the desired mode of operation. When the R/W input is at logic "0" the chip is in the write enable mode of operation. The outputs (0_1 –0_8) are disabled (floating) with the corresponding pins becoming the data inputs ($0_1 \rightarrow D_{IN\ 1}$ etc.). The word address is selected in the same manner as in the read mode. Data to be programmed are presented 8 bits in parallel and after the address and data are set up a programming pulse (V_P –50 volts) is applied. V_{PROG} electrically writes the data into the memory array. Writing may be inhibited by deselecting the chip with the CS input at a logic "1" during the write cycle. This feature allows true "on board" programming in bus organized systems where the R/W and V_{PROG} inputs are common and the device to be programmed is selected by means of the chip select input as during read operations.

The amount of program energy required to insure memory retention may be defined as a function of the number of program pulses (N) times the program pulse width (t_{pw}) ($N \times t_{pw} \geqslant 60$ msec). This means if a 3 ms pulse is used, 20 program pulses are required, and if a 5 ms pulse is used 12 program pulses are required.

The read operation is accomplished by a logic "1" at the R/W input with the program input connected to V_{SS} potential. True data (data out = data in) is valid after the address is stable. The CS input will disable (float) the outputs when at a logic "1" to allow or tie capability.

Erasure is accomplished by exposing the array to a high intensity ultra-violet light source (such as, Ultra-Violet Products, Inc. Lamp Model S52 or UVS-54) for a period of 7 to 10 minutes. The clear optical lid should be approximately one inch away from the lamp tubes.

INTERFACE DESCRIPTION

Pin	Label	Function
(2)	D0	**Data Lines** – with the R/W line selected for Read (V_{IH}), the Data Lines (D0 through D7) are set to reflect the contents of the selected memory location. When the R/W line is set for Write (V_{IL}), the Data Lines are input to the addressed location of the 6834 when V_{PROG} is present. The Data Bus output drivers are three-state devices that remain in the high impedance (off) state when CS is in the V_{IH} state of when R/W is in the V_{IL} state.
(3)	D1	
(4)	D2	
(5)	D3	
(6)	D4	
(7)	D5	
(8)	D6	
(9)	D7	
(14)	R/W	**Read/Write** – When this input line is set to V_{IH}, the device is in the Read mode, a low (V_{IL}) signal puts it into the Write mode.
(15)	CS	**Chip Select** – This input line must be set to V_{IL} for a Read or Write operation to be performed. When it is High (V_{IH}) the output data bus is set to a high-impedance three-state condition and disables the Write operation.
(11)	V_{PROG}	**Program** – In the Write mode, a programming pulse (–50V dc) at this input causes the data at the Data Lines to be stored in the selected address. This pin should be tied to V_{CC} for normal Read operations.
(24)	A0	**Address Lines** – These lines select the 8 bit word in memory for Read or Write operation

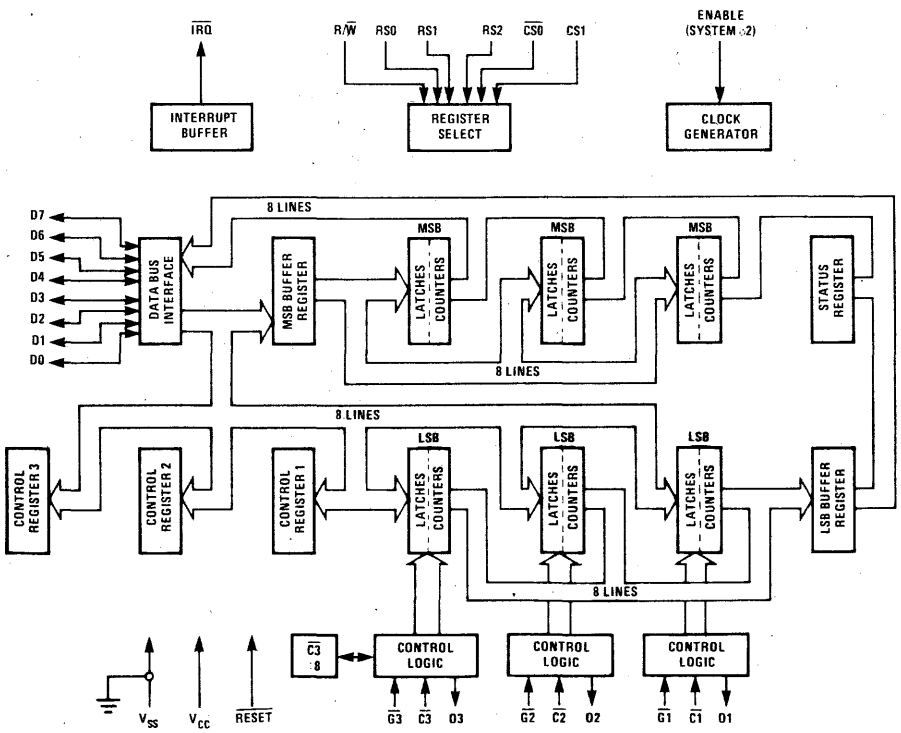
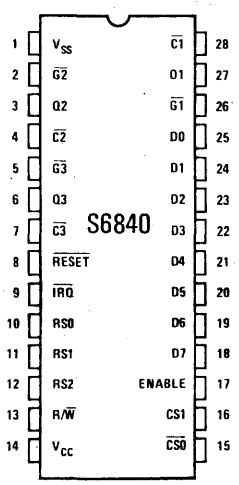
PROGRAMMABLE TIMER

Features



- ☐ Operates from a Single 5 Volt Power Supply
- ☐ Fully TTL Compatible
- ☐ Single System Clock Required (Enable)
- ☐ Selectable Prescaler on Timer 3 Capable of a 4MHz Input
- ☐ Programmable Interrupts ($\overline{IRQ}$) Output to MPU
- ☐ Readable Down Counter Indicates Counts to Go to Time-Out
- ☐ Selectable Gating for Frequency or Pulse-Width Comparison
- ☐ $\overline{RESET}$ Input
- ☐ Three Asynchronous External Clock and Gate/Trigger Inputs Internally Synchronized
- ☐ Three Maskable Outputs

General Description



The S6840 is a programmable subsystem component of the S6800 family designed to provide variable system time intervals.

The S6840 has three 16-bit binary counters, three corresponding control registers and a status register. These counters are under software control and may be used to cause system interrupts and/or generate output signals. The S6840 may be utilized for such tasks as frequency measurements, event counting, interval measuring and similar tasks. The device may be used for square wave generation, gated delay signals, single pulses of controlled duration, and pulse width modulation as well as system interrupts.

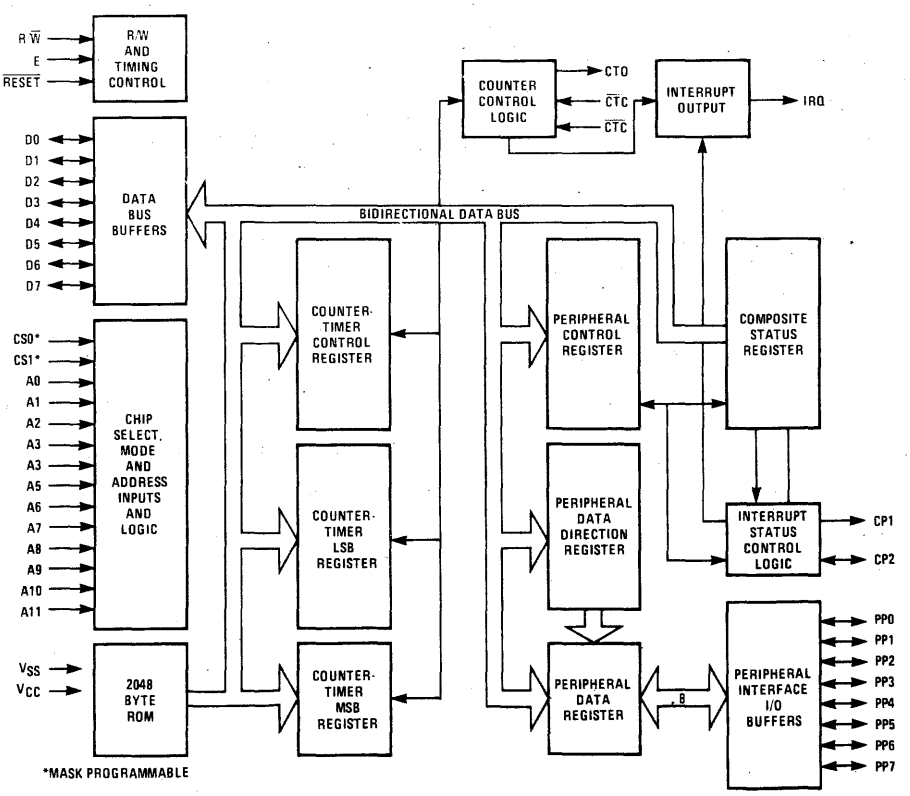
ROM-I/O-TIMER

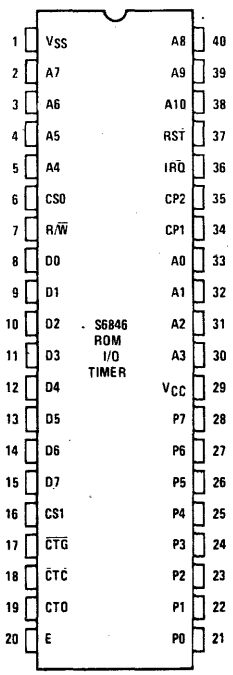
Features

- 2048x8-Bit Bytes of Mask-Programmable ROM
- 8-Bit Bidirectional Data Port for Parallel Interface Plus Two Control Lines
- Programmable Interval Timer-Counter Functions
- Programmable I/O Peripheral Data, Control and Direction Registers
- Compatible with the Complete S6800 Microcomputer Product Family
- TTL-Compatible Data and Peripheral Lines
- Single 5 Volt Power Supply



General Description

The S6846 combination chip provides the means, in conjunction with the S6802, to develop a basic 2-chip microcomputer system. The S6846 consists of 2048 bytes of mask-programmable ROM, an 8-bit bidirectional data port with control lines, and a 16-bit programmable timer-counter.



This device is capable of interfacing with the S6802 (basic S6800, clock and 128 bytes of RAM) as well as the S6800 if desired. No external logic is required to interface with most peripheral devices.

The S6846 combination chip may be partitioned into three functional operating sections: programmed storage, timer-counter functions, and a parallel I/O port.

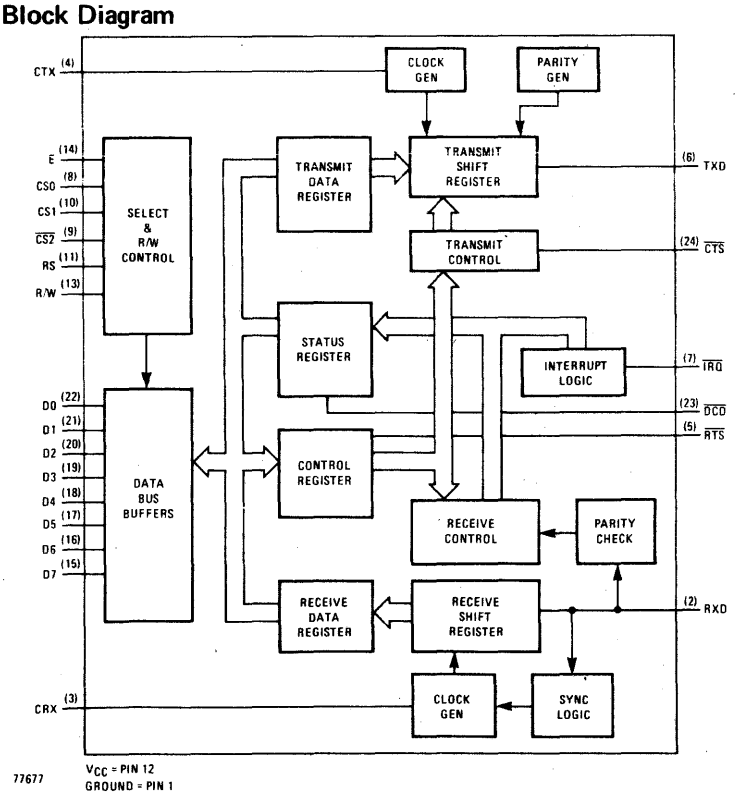
Asynchronous Communication Interface Adapter (ACIA)

Features

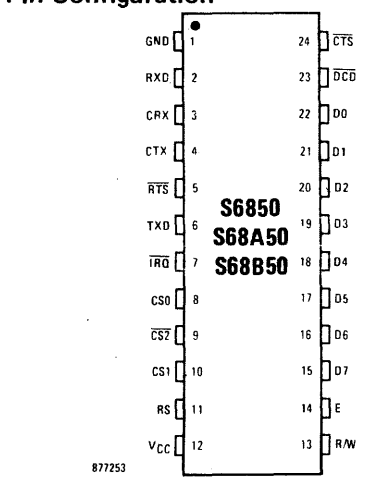
- 8 Bit Bidirectional Data Bus for Communication with MPU
- False Start Bit Deletion
- Peripheral/Modem Control Functions
- Double Buffered Receiver and Transmitter
- One or Two Stop Bit Operation
- Eight and Nine-Bit Transmission with Optional Even and Odd Parity
- Parity, Overrun and Framing Error Checking
- Programmable Control Register
- Optional ÷1, ÷16, and ÷64 Clock Modes
- Up to 500,000 bps Transmission

Absolute Maximum Ratings



Supply Voltage	-0.3V to +7.0V
Input Voltage	-0.3V to +7.0V
Operating Temperature Range	0°C to +70°C
Storage Temperature Range	-55°C to +150°C

General Description



The S68A50/S68B50 Asynchronous Communications Interface Adapter (ACIA) provides the data formatting and control to interface serial asynchronous data communications to bus organized systems such as the S68A00/S68B00 Microprocessing Units.

The S68A50/S68B50 includes select enable, read/write, interrupt and bus interface logic to allow data transfer over an eight-bit bidirectional data bus. The parallel data of the bus system is serially transmitted and received by the asynchronous data interface, with proper formatting and error checking. The functional configuration of the ACIA is programmed via the data bus during system initialization. Word lengths, clock division ratios and transmit control through the Request to Send output may be programmed. For modem operation three control lines are provided.

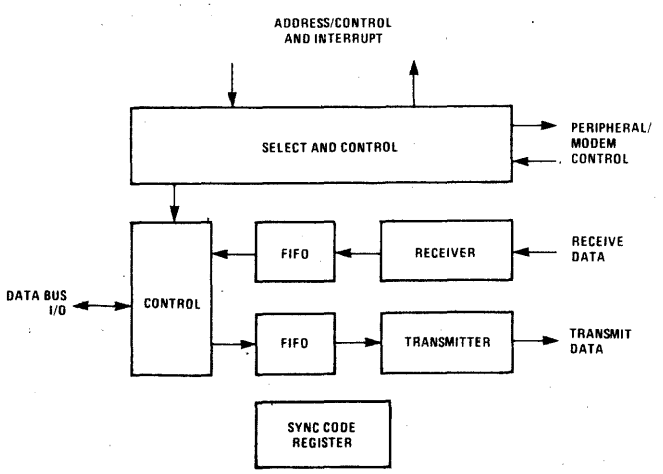
SYNCHRONOUS SERIAL DATA ADAPTER (SSDA)

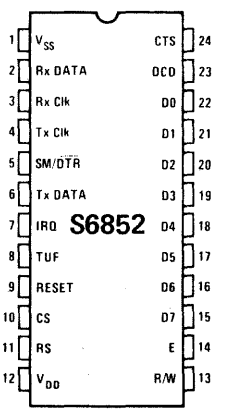
Features

- ☐ Programmable Interrupts from Transmitter, Receiver, and Error Detection Logic
- ☐ Character Synchronization on One or Two Sync Codes
- ☐ External Synchronization Available for Parallel-Serial Operation
- ☐ Programmable Sync Code Register
- ☐ Up to 600kbps Transmission
- ☐ Peripheral/Modem Control Functions
- ☐ Three Bytes of FIFO Buffering on Both Transmit and Receive
- ☐ Seven, Eight, or Nine Bit Transmission
- ☐ Optional Even and Odd Parity
- ☐ Parity, Overrun, and Underflow Status



General Description

The S6852 Synchronous Serial Data Adapter provides a bi-directional serial interface for synchronous data information interchange. It contains interface logic for simultaneously transmitting and receiving standard synchronous communications characters in bus organized systems such as the S6800 Microprocessor systems.



The bus interface of the S6852 includes select, enable, read/write, interrupt, and bus interface logic to allow data transfer over an 8-bit bi-directional data bus. The parallel data of the bus system is serially transmitted and received by the synchronous data interface with synchronization, fill character insertion/deletion, and error checking. The functional configuration of the SSDA is programmed via the data bus during system initialization. Programmable control registers provide control for variable word lengths, transmit control, receive control, synchronization control, and interrupt control. Status, timing and control lines provide peripheral or modem control.

Typical applications include floppy disk controllers, cassette or cartridge tape controllers, data communications terminals, and numerical control systems.

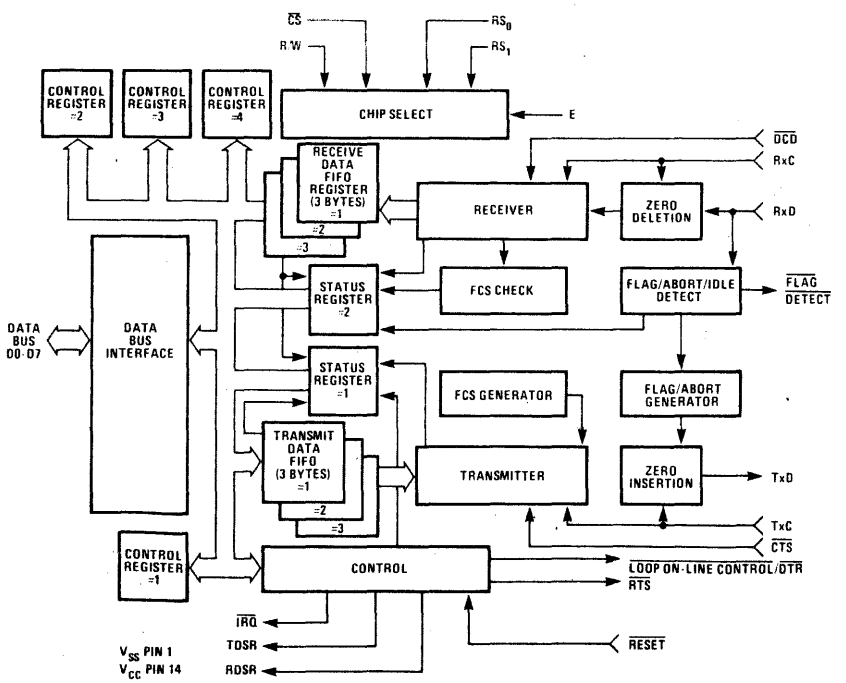
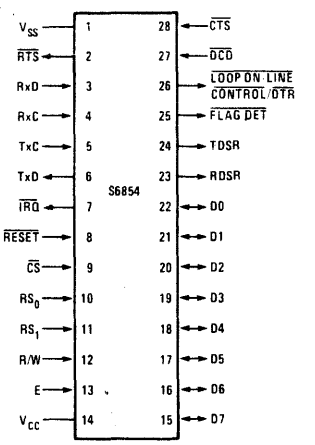
ADVANCED DATA LINK CONTROLLER



Features

- ☐ S6800 Compatible
- ☐ Protocol Features
  - ☐ Automatic Flag Detection and Synchronization
  - ☐ Zero Insertion and Deletion
  - ☐ Extendable Address, Control and Logical Control Fields (Optional)
  - ☐ Variable Word Length Info Field — 5, 6, 7, or 8-bits
  - ☐ Automatic Frame Check Sequence Generation and Check
  - ☐ Abort Detection and Transmission
  - ☐ Idle Detection and Transmission
- ☐ Loop Mode Operation
- ☐ Loop Back Self-Test Mode
- ☐ NRZ/NRZI Modes
- ☐ Quad Data Buffers for Each Rx and Tx
- ☐ Prioritized Status Register (Optional)
- ☐ MODEM/DMA/Loop Interface
- ☐ MIL-STD-883, Class B and C Devices Available



General Description

The S6854 ADLC performs the complex MPU/data communication link function for the "Advanced Data Communication Control Procedure" (ADCCP). High Level Data Link Control (HDLC) and Synchronous Data Link Control (SDLC) standards. The ADLC provides key interface requirements with improved software efficiency. The ADLC is designed to provide the data communications interface for both primary and secondary stations in stand-alone, polling, and loop configurations.

S68047

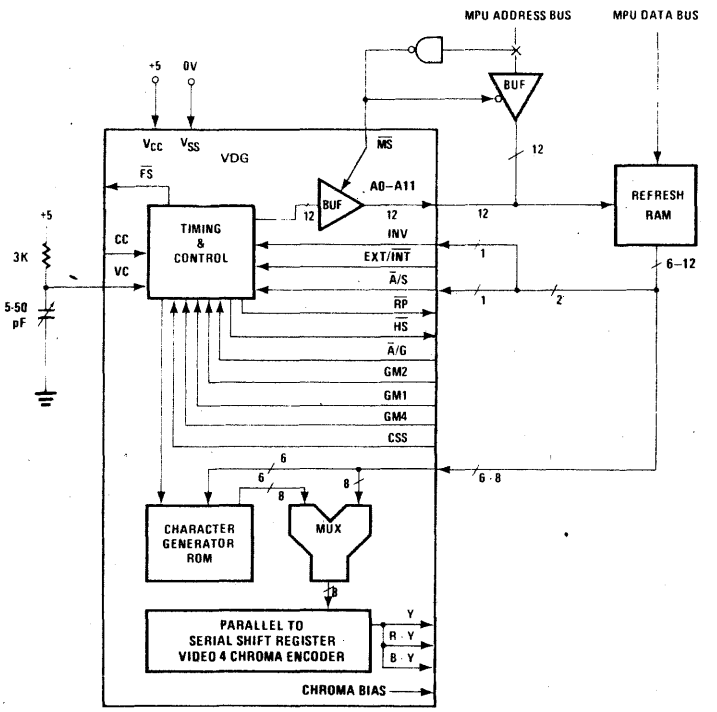
VIDEO DISPLAY GENERATOR

August 1978

Features

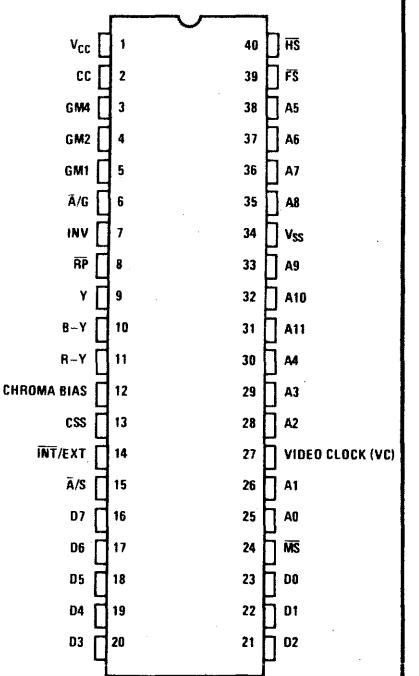
- ☐ 32 x 16 (512 total) Alphanumeric Two Color Display on Black Background with Internal or External Character Generator ROM.
- ☐ Two Semigraphics Modes with Display Densities Ranging from 64 x 32 to 64 x 48 in 8 and 4 Color Sets Respectively, plus Black.
- ☐ Full Graphics Modes with Display Densities Ranging from 64 x 64 to 256 x 192 in 2 and 4 Colors.
- ☐ Full NTSC Compatible Composite Video with Choice of Interlaced and Non-interlaced Display Versions.
- ☐ Provides Microprocessor Compatible Interface Signals.
- ☐ Generates Display Refresh RAM Addresses.
- ☐ NMOS Device, Single 5V Supply, TTL Compatible Logic Levels.
- ☐ Color Set Select Pin Can Give 8 Color Displays in Full Graphics Mode.

General Description



The S68047 Video Display Generator (VDG) is designed to produce composite video suitable for display on a standard American NTSC compatible black/white television or color televison or monitor.

There are three major types of display which the S68047 can generate. These include an alphanumerics mode of which there are two types, each with normal or inverted video; a semigraphics mode of which there are also two types; and full graphics mode of which there are eight types.



Alphanumeric Modes

The alphanumeric modes, internal and external, enable the S68047 to display a matrix of 32 x 16 (512 total) characters. The internal mode utilizes an on-chip 64 ASCII character ROM to display each character in a 5 x 7 dot matrix font. In the external alphanumeric

Block Diagram

Pin Configuration

MICROPROCESSOR AMI

ADVANCED PRODUCT DESCRIPTION

©IC MASTER 1979

General Description (Continued)

mode, an external memory is required, either ROM or RAM, which is used to display the 32 x 16 character matrix with each character located within an 8 x 12 dot matrix of customized font. Switching between internal and external alphanumerics modes and normal and inverted video can be accomplished on a character by character basis.

Semigraphic Modes

The two semigraphic modes, semigraphic 4 (SG4) and semigraphic 6 (SG6), subdivide each of the 512 (32 x 16) character blocks of 8 x 12 dots each into 2 x 2 and 2 x 3 smaller blocks respectively. In SG4 each block is created from 4 x 6 dots and in SG6 each block consists of 4 x 4 dots. In addition the SG4 and SG6 modes can each be displayed in 8 and 4 colors plus black.

Display switching from alphanumerics to semigraphics modes or vice versa during a raster display is called minor mode switching and can take place on a character basis.

Graphics Modes

The eight full graphics modes are divided into two major groups, 4 color and 2 color. The 4 color graphics provide 4 display densities ranging from 64 x 64 for Graphics 0 through to 128 x 192 elements for Graphics 6. The 2 color graphics also provide 4 display densities ranging from 128 x 64 for Graphics 1 through to 256 x 192 elements for Graphics 7. The latter display has the highest density of the eight graphics modes. The amount of display memory increases proportionately with increasing density of display to a maximum of 6K bytes for Graphics 7. Switching between either the alphanumeric modes or semigraphics modes and any of the full graphics modes is called major mode switching. Major mode switching can only occur at the end of every twelfth raster line scan.

Applications

Anywhere data can be more usefully presented graphically on a CRT and for a minimum cost, the VDG in conjunction with a microprocessor based controller can utilize a standard American NTSC compatible TV or monitor for such a purpose. Applications are extremely broad ranging from educational systems, video games, small low cost business/home computers to process control monitors and medical diagnostic displays.

The different modes of operation permit various cost/display presentation tradeoffs. The alphanumerics modes allow use of the TV screen as a video teletype at the most limited level of operation. Only 512 bytes, one for each character, need to be stored, each byte being a minimum of six bits wide per the ASCII code. If video inversion switching or alpha to semigraphics switching is required per character then two extra bits are required in the display RAM as shown in Fig. 5. The semigraphics modes each offer an intermediate range of graphics densities with tradeoffs in density versus color. Typical semigraphics display capabilities are bar graphs, charts, mini displays, etc. which with minor mode switching to alphanumerics modes allow annotation or captioning of the resultant display. The various graphics modes provide greater density displays with greater freedom of display presentations. The tradeoffs in increasing density are with increasing display memory size and color versus density. A minimum Graphics 0 provides a display density of 64 x 64 (4096) elements, each element being composed of a matrix of 12 (4 x 3) dots with a selection of four colors per element. Since each of the even numbered 4 color graphics modes map two bits of the data word to one picture element, each data word of memory provides four picture elements. Thus Graphics 0 requires 4096/4 = 1024 bytes of display RAM, Graphics 2 requires 8192/4 = 2048 and so on. Graphics 1, like all the odd numbered 2 color graphics modes, maps one bit of data word to one picture element. Each data word therefore maps eight elements. Graphics 1 density of 128 x 8 (8192) elements therefore requires 8192/8 = 1024 bytes of display RAM and Graphics 7, the densest display, requires 49, 152/8 = 6144 bytes of RAM. At the higher density graphics displays, the rate of change of elements approaches the maximum dot frequency of 6MHz. This video rate taxes the capabilities of most commercially available television sets and thus the quality of the display system (television or monitor) should be commensurate with the highest video rate to be used.

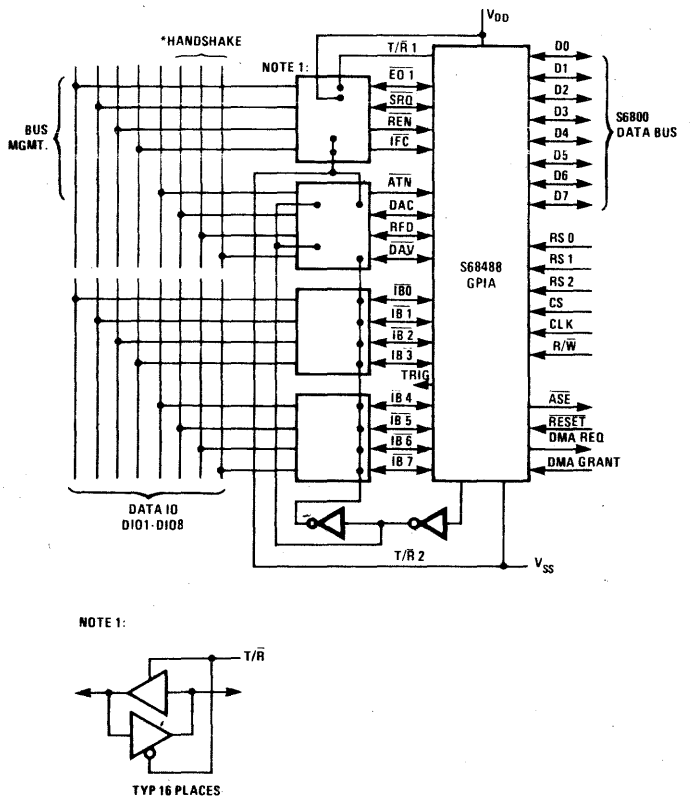
S68488

GENERAL PURPOSE INTERFACE ADAPTER

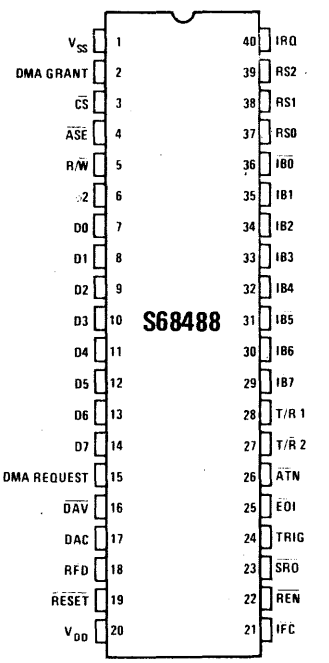
Features



- ☐ Single or Dual Primary Address Recognition
- ☐ Secondary Address Capability
- ☐ Complete Source and Acceptor Handshakes
- ☐ Programmable Interrupts
- ☐ RFD Holdoff to Prevent Data Overrun
- ☐ Operates with DMA Controller
- ☐ Serial and Parallel Polling Capability
- ☐ Talk-Only or Listen-Only Capability
- ☐ Selectable Automatic Features to Minimize Software
- ☐ Synchronization Trigger Output
- ☐ S6800 Bus Compatible

General Description

The S68488 GPIA provides the means to interface between the IEEE488 standard instrument bus and the S6800. The 488 instrument bus provides a means for controlling and moving data from complex systems of multiple instruments.



The S68488 will automatically handle all handshake protocol needed on the instrument bus.

Block Diagram

*The 3-wire handshake described is the subject of patents owned by Hewlett-Packard Co.

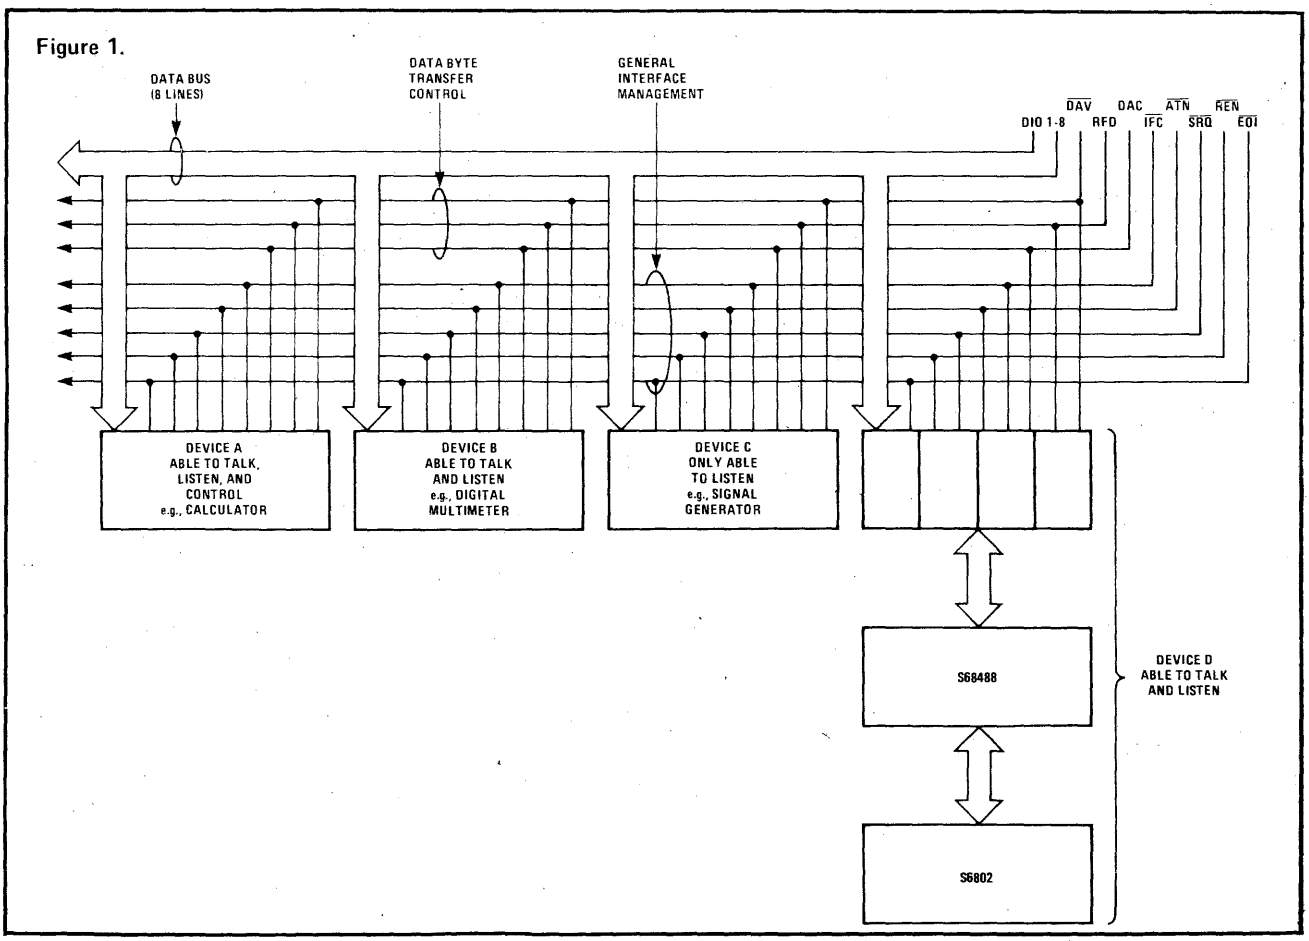
Pin Configuration

ADVANCED PRODUCT DESCRIPTION

©IC MASTER 1979

Functional Description

The IEEE 488 instrument bus standard is a bit-parallel, byte-serial bus structure designed for communiation to and from intelligent instruments. Using this standard, many instruments may be interconnected and remotely and automatically controlled or programmed. Data may be taken from, sent to, or transferred between instruments. A bus controller dictates the role of each device by making the attention line true and sending talk or listen addresses on the instrument bus data lines; those devices which have matching addresses are activated. Device addresses are set into each GPIA from switches or jumpers on a PC board by a microprocessor as a part of the initialization sequence.



When the controller makes the attention line true, instrument bus commands may also be sent to single or multiple GPIAs.

Information is transmitted on the instrument bus data lines under sequential control of the three handshake lines. No step in the sequence can be initiated until the previous step is completed. Information transfer can proceed as fast as the devices can respond, but no faster than the slowest device presently addressed as active. This permits several devices of different speeds to receive the same data concurrently.

The GPIA is designed to work with standard 488 bus driver Ics (S3448As) to meet the complete electrical specifications of the IEEE488 bus. Additionally, a powered-off instrument may be powered-on without disturbing the 488 bus. With some additional logic, the GPIA could be used with other microprocessors.

The S68488 GPIA has been designed to interface between the S6800 microprocessor and the complex protocol of the IEEE488 instrument bus. Many instrument bus protocol functions are handled automatically by the GPIA and require no additional MPU action. Other functions require minimum MPU response due to a large number of internal registers conveying information on the state of the GPIA and the instrument bus.

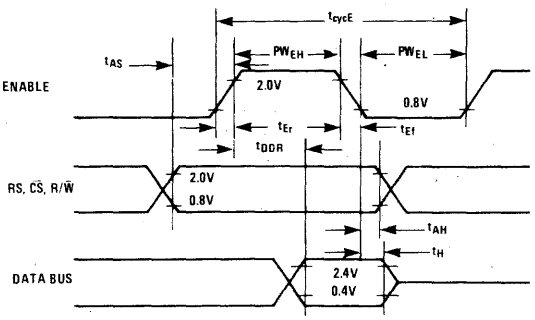

Figure 4. Bus Write Timing Characteristics (Write Information into GPIA)

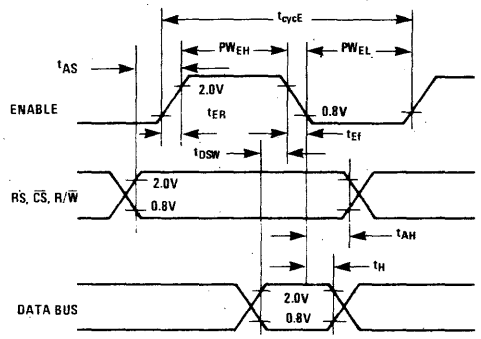

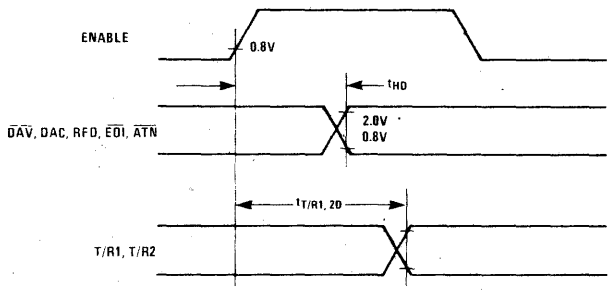

Figure 5. Output Bus Timing

A.C. Time Values

Symbol*	Parameter		Min.	Typ.	Max.	Unit	Conditions
T_1	Settling Time for Multiple Message	SH		⩾2		μs**	
t_2	Response to $\overline{ATN}$	SH, AH, T, L		⩽200		ns	
T_3	Interface Message Accept Time †	AH		>0		∮	
t_4	Response to $\overline{IFC}$ or $\overline{REN}$ False	T, TE, L, LE		<100		μs	
t_5	Response to $\overline{ATN} \bullet \overline{EOI}$	PP		⩽200		ns	

* Time values specified by a lower case t indicate the maximum time allowed to make a state transition. Time values specified by an upper case T indicate the minimum time that a function must remain in a state before exiting.

** If three-state drivers are used on the $\overline{DIO} - \overline{DAV}$ and $\overline{EOI}$ lines, T_1 may be:
(1) ⩾1100ns
(2) Or ⩾700ns if it is known that within the controller $\overline{ATN}$ is driven by a three-state driver.
(3) Or ⩾500ns for all subsequent bytes following the first sent after each false transition of $\overline{ATN}$ [the first byte must be sent in accordance with (1) or (2)].

† Time required for interface functions to accept, not necessarily respond to interface messages.

∮ Implementation dependent.

MPU bus clock rate — The current 6800 bus clock is ⩽ 1MHz but part should operate at 1.5MHz (design goal), with appropriate settling times (T1).

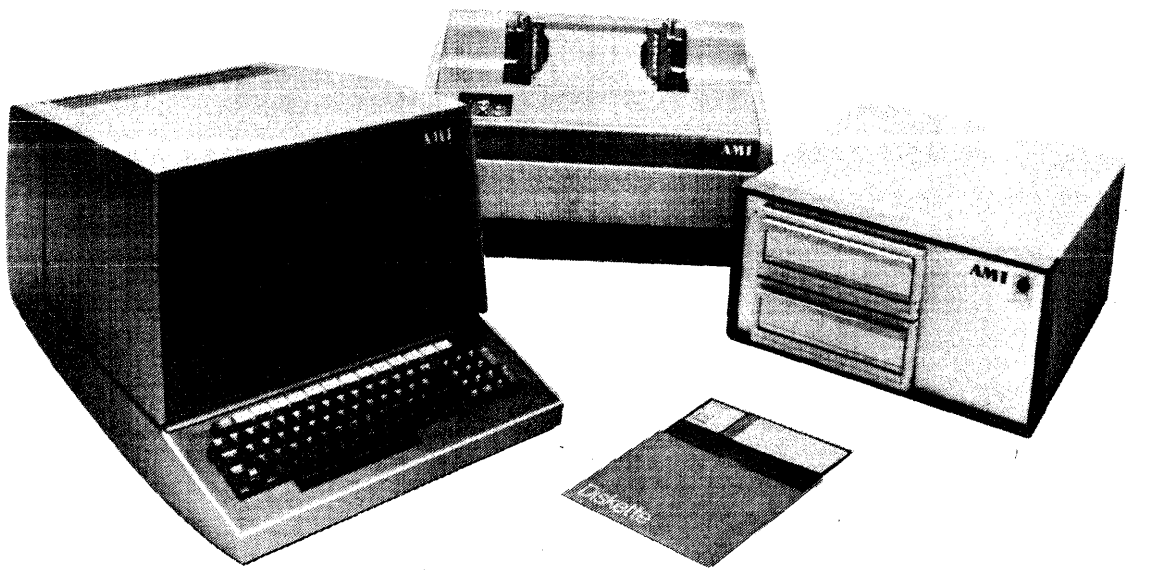
MDC BASIC INTERPRETER

September 1978



Features

- ☐ **Reduces Software Effort**
- ☐ **Easy Source Code Manipulation**
- ☐ **Instant Program Corrections**
- ☐ **Full Debug Package**
- ☐ **Allows Calls to Machine-Language Subroutine**

General Description

The MDC BASIC Interpreter (SFT27100) operates with AMI's MDC-100 Microcomputer development system to provide an easy to use high level language for performing computation and control functions in the MDC.

MDC BASIC (supplied on floppy disk) is used to edit, translate, debug and execute user-written ASCII source programs in read/write memory (RAM). Each BASIC statement is translated from its ASCII format and then executed by the BASIC interpreter on a line-by-line basis. Because the interpreter executes each line, the need to translate to machine code is avoided. This approach eases source code manipulation, because it is always in memory, and allows instant revision of the program when errors are detected.

ADVANCED PRODUCT DESCRIPTION

©IC MASTER 1979

Functional Description

MDC BASIC operates in two modes. In program mode each statement is preceded by a line number. This causes the source statement to be stored in memory for later execution. Statements are stored in increasing order based upon the line number. If no line number precedes the statement, it is executed immediately without being placed in memory. This latter mode, known as "direct" or "immediate", is a means of rapidly gaining solutions to problems where complexity is not great enough to require a program solution. In addition, all control commands are entered in direct mode.

These commands specify actions which alter the status of the user's program; for example, they direct the retrieval, storing and execution on programs. Program statements are summarized in Table 1; control commands are summarized in Table 2.

The BASIC interpreter is loaded in RAM from $20 to $3000.MDC BASIC relies on the intrinsic functions of the MDC-100 for all I/O.

Table 1

ABS — ABSolute value function
ASC — string to ASCII decimal functions
ATAN — arc tangent function
CHR$ — decimal ASCII to string function
CLOSEFILE — close open file verb
CNO (N) — change closed OLD to NEW
COS — COSine function
DATA — internal data list statement
DEF FNA (X) — built in function
DIGITS — numeric display precision
DIM — reserve array storage statement
END — end BASIC program statement
EOFF (N) — test end of file function
EXP (X) — EXPonential base e function
FOR — loop control statement
GOTO — unconditional transfer statement
GOSUB — subroutine call statement
INPUT — request input statement
INT — integer function
LEFT$ — extract substring function
LEN — length of string function
LET — assignment statement
LOG (X) — log base 10 function
MID$ — extract substring function
NEXT — close FOR loop statement
ON — case statement for GOSUB, GOTO
OPENFILE — open data file
PEEK — display memory function
POKE — modify memory function
POS — current print POSition function
PRINT — output statement
READ — read from DATA list statement
REM — REMark (comment) statement
RESTORE — rewind DATA list statement
RESTR (N) — rewind file statement
RETURN — return from GOSUB call
RIGHT$ — extract substring function
RND — RaNDom number function
SGN — SiGNum function
SIN — SINe function
STOP — halt execution statement
STRING — set global string length verb
STR$ — convert numeric to string function
SQR — SQuaRe root function
TAB — print space to column function
TAN — TANgent function
TRACEOFF — cease line trace verb
TRACEON — initiate line trace verb
VAL — convert string to numeric function
USER — call machine language routine

Table 2

ATTACH —
FILETABLE — display file table verb
LIB (N) — display disk directory verb
LINE — set display width verb
LOAD — fetch binary program file from disk
PATCH — return to FDOS verb
PORT — change control port verb
RUN — begin execution of program
SCRATCH — delete current program
TRACEOFF — cease line trace verb
TRACEON — initiate line trace verb
NEW — delete current program verb

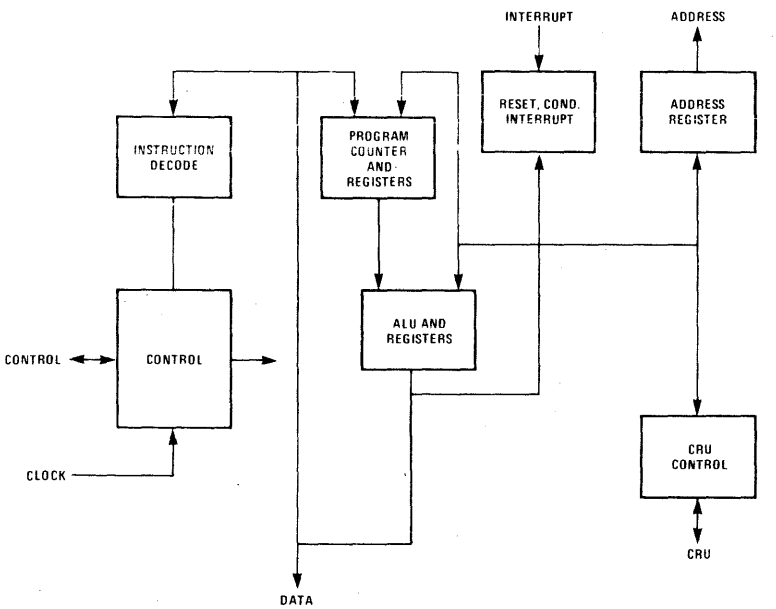
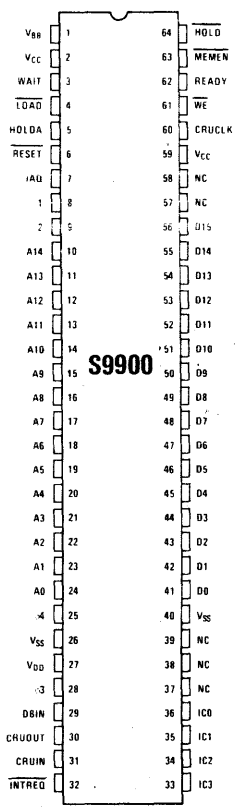
16-BIT MICROPROCESSOR



Features

- ☐ 16-Bit Instruction Word
- ☐ Full Minicomputer Instruction Set Capability including Multiply and Divide
- ☐ Up to 65,536 Bytes of Memory
- ☐ 3.3MHz Speed
- ☐ Advanced Memory-to-Memory Architecture
- ☐ Separate Memory, I/O and Interrupt-Bus Structures
- ☐ 16 General Registers
- ☐ 16 Prioritized Interrupts
- ☐ Programmed and DMA I/O Capability
- ☐ N-Channel Silicon-Gate Technology



General Description

The S9900 microprocessor is a single-chip 16-bit central processing unit (CPU) produced using N-channel silicon-gate MOS technology. The instruction set of the S9900 includes the capabilities offered by full minicomputers. The unique memory-to-memory architecture features multiple register files, resident in memory, which allow faster response to interrupts and increased programming flexibility. The separate bus structure simplifies the system design effort. AMI provides a compatible set of MOS memory and support circuits to be used with an S9900 system. The system is fully supported by software and complete prototyping systems.

S9900 Electrical and Mechanical Specifications

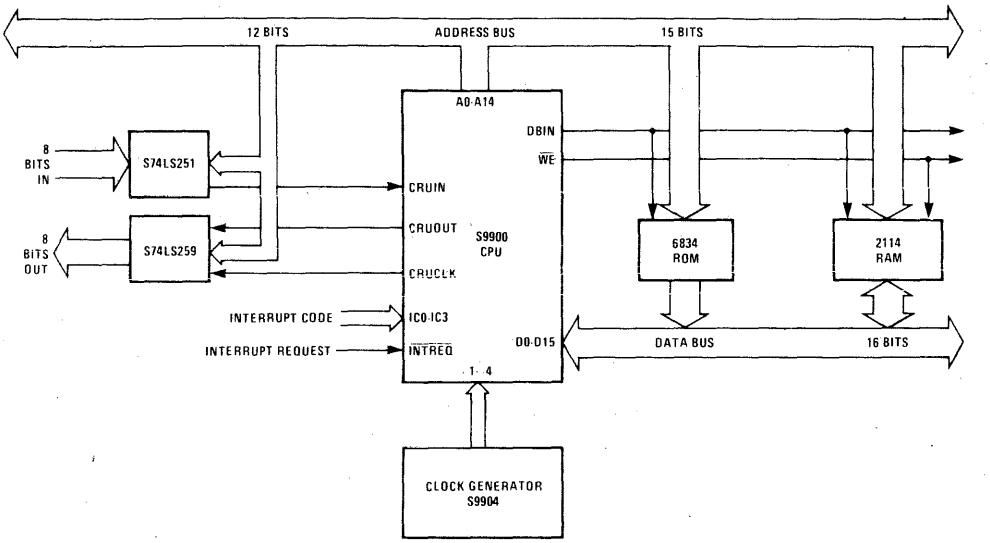
Absolute Maximum Ratings Over Operating Free-Air Temperature Range (unless otherwise noted)*

Supply Voltage, V_{CC} (See Note 1) ..... −0.3V to +20V
Supply Voltage, V_{DD} (See Note 1) ..... −0.3V to +20V
Supply Voltage, V_{SS} (See Note 1) ..... −0.3V to +20V
All Input Voltages (See Note 1) ..... −0.3V to +20V
Output Voltage (with Respect to V_{SS}) ..... −2V to +7V
Continuous Power Dissipation ..... +1.2W
Operating Free-Air Temperature Range ..... 0°C to +70°C
Storage Temperature Range ..... −55°C to +150°C

*Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

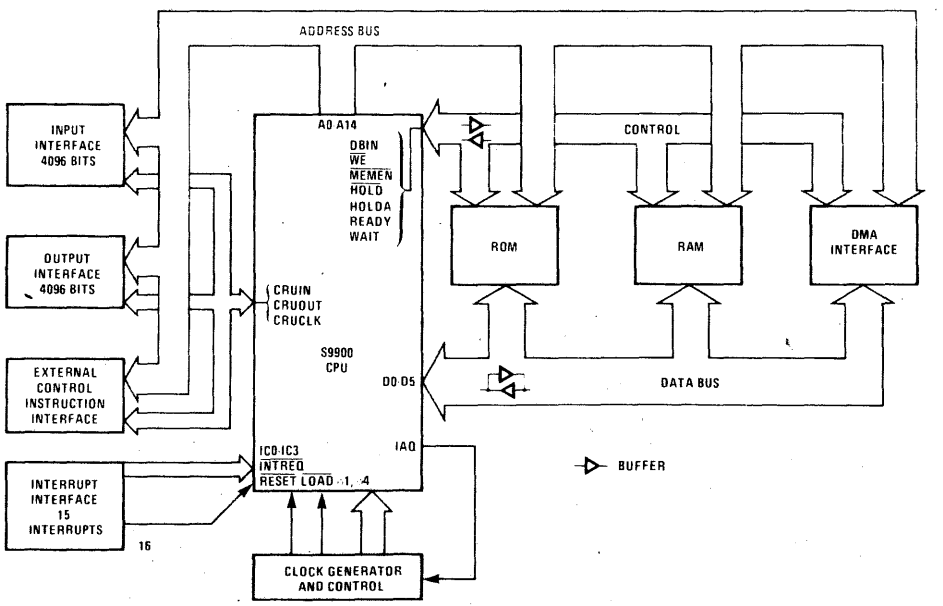
NOTE 1: Under absolute maximum ratings voltage values are with respect to the most negative supply, V_{BB} (substrate), unless otherwise noted. Throughout the remainder of this section, voltage values are with respect to V_{SS}.

Recommended Operating Conditions



Symbol	Parameter	Min.	Nom.	Max.	Unit	Conditions
V_{BB}	Supply voltage	-5.25	-5	-4.75	V	
V_{CC}	Supply voltage	4.75	5	5.25	V	
V_{DD}	Supply voltage	11.4	12	12.6	V	
V_{SS}	Supply voltage		0		V	
V_{IH}	High-level input voltage (all inputs except clocks)	2.2	2.4	V_{CC}+1	V	
$V_{IH(\phi)}$	High-level clock input voltage	V_{DD}-2		V_{DD}	V	
V_{IL}	Low-level input voltage (all inputs except clocks)	-1	0.4	0.8	V	
$V_{IL(\phi)}$	Low-level clock input voltage	-0.3	0.3	0.6	V	
T_A	Operating free-air temperature	0		70	°C	

Timing Requirements Over Full Range of Recommended Operating Conditions (See Figures 1 and 2)



Symbol	Parameter	Min.	Nom.	Max.	Unit	Conditions
$t_{c(\phi)}$	Clock cycle time	0.3	0.333	0.5	μs	
$t_{r(\phi)}$	Clock rise time	10	12		ns	
$t_{f(\phi)}$	Clock fall time	10	12		ns	
$t_{w(\phi)}$	Pulse width, any clock high	40	45	100	ns	
$t_{\phi 1L, \phi 2H}$	Delay time, clock 1 low to clock 2 high (time between clock pulses)	0	5		ns	
$t_{\phi 2L, \phi 3H}$	Delay time, clock 2 low to clock 3 high (time between clock pulses)	0	5		ns	
$t_{\phi 3L, \phi 4H}$	Delay time, clock 3 low to clock 4 high (time between clock pulses)	0	5		ns	
$t_{\phi 4L, \phi 1H}$	Delay time, clock 4 low to clock 1 high (time between clock pulses)	0	5		ns	
$t_{\phi 1H, \phi 2H}$	Delay time, clock 1 high to clock 2 high (time between leading edges)	70	80		ns	
$t_{\phi 2H, \phi 3H}$	Delay time, clock 2 high to clock 3 high (time between leading edges)	70	80		ns	
$t_{\phi 3H, \phi 4H}$	Delay time, clock 3 high to clock 4 high (time between leading edges)	70	80		ns	
$t_{\phi 4H, \phi 1H}$	Delay time, clock 4 high to clock 1 high (time between leading edges)	70	80		ns	
t_{su}	Data or control setup time before clock 1	30			ns	
t_h	Data hold time after clock 1	10			ns

Architecture

Registers and Memory

The S9900 employs an advanced memory-to-memory architecture. Blocks of memory designated as workspace replace internal-hardware registers with program-data registers. The memory word of the S9900 is 16 bits long. Each word is also defined as 2 bytes of 8 bits. The instruction set of the S9900 allows both word and byte operands. Thus, all memory locations are on even address boundaries and byte instructions can address either the even or odd byte. The memory space is 65,536 bytes or 32,768 words. The word and byte formats are shown below.

The S9900 memory map is shown in Figure 8. The first 32 words are used for interrupt trap vectors. The next contiguous block of 32 memory words is used by the extended operation (XOP) instruction for trap vectors. The last two memory words, $FFFC_{16}$ and $FFFE_{16}$, are used for the trap vector of the LOAD signal. The remaining memory is then available for programs, data, and workspace registers. If desired, any of the special areas may also be used as general memory.

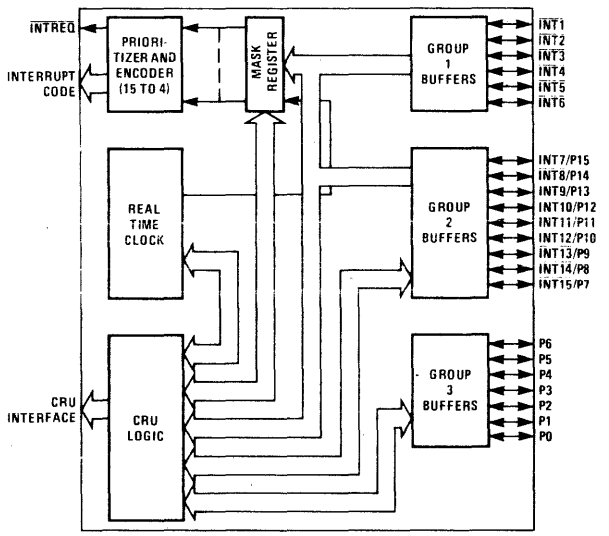
Programmable Systems Interface Circuit



Features

- N-channel Silicon-Gate Process
- 9900 Series CRU Peripheral
- Performs Interrupt and I/O Interface Functions
  - 6 Dedicated Interrupt Input Lines
  - 7 Dedicated I/O Ports
  - 9 Ports Programmable as Interrupts or I/O
- Easily Stacked for Interrupt and I/O Expansion
- Interval and Event Timer
- Single 5V Supply

General Description

The S9901 Programmable Systems Interface is a multifunctioned component designed to provide low cost interrupts and I/O ports in a 9900/9980 microprocessor system. It is fabricated with N-channel silicon-gate technology and is completely TTL compatible on all inputs including the power supply (+5V) and single-phase clock. Figure 1 is a block diagram of the S9901. The Programmable Systems Interface provides a 9900/9980 system with interrupt control, I/O ports, and a real-time clock as shown in Figure 2.

S9901 PIN ASSIGNMENTS AND FUNCTIONS

SIGNATURE	PIN	I/O	DESCRIPTION
$\overline{\text{INTREQ}}$	11	OUT	INTERRUPT Request. When active (low) $\overline{\text{INTREQ}}$ indicates that an enabled interrupt has been received. $\overline{\text{INTREQ}}$ will stay active until all enabled interrupt inputs are removed.
IC0 (MSB)	15	OUT	Interrupt Code lines. IC0-IC3 output the binary code corresponding to the highest priority enabled interrupt. If no enabled interrupts are active IC0-IC3 = (1, 1, 1, 1).
IC1	14	OUT	
IC2	13	OUT	
IC3 (LSB)	12	OUT	
$\overline{\text{CE}}$	5	IN	Chip Enable. When active (low) data may be transferred through the CRU interface to the CPU. $\overline{\text{CE}}$ has no effect on the interrupt control section.
S0	39	IN	Address select lines. The data bit being accessed by the CRU interface is specified by the 5-bit code appearing on S0-S4.
S1	36	IN	
S2	36	IN	
S3	25	IN	
S4	24	IN	
CRUIN	4	OUT	CRU data in (to CPU). Data specified by S0-S4 is transmitted to the CPU by CRUIN. When $\overline{\text{CE}}$ is not active CRUIN is in a high-impedance state.
CRUOUT	2	IN	CRU data out (from CPU). When $\overline{\text{CE}}$ is active, data present on the CRUOUT input will be sampled during CRUCLK and written into the command bit specified by S0-S4.
CRUCLK	3	IN	CRU Clock (from CPU). CRUCLK specifies that valid data is present on the CRUOUT line.
$\overline{\text{RST}}1$	1	IN	Power Up Reset. When active (low) $\overline{\text{RST}}1$ resets all interrupt masks to "0", disables the clock, and programs all I/O ports to inputs. $\overline{\text{RST}}1$ has a Schmitt-Trigger input to allow implementation with an RC circuit as shown in Figure 6.
V_{CC}	40		Supply Voltage. +5V nominal.
V_{SS}	16		Ground Reference.
$\overline{\phi}$	10		System clock ($\overline{\phi}3$ in S9900 system, $\overline{\text{CKOUT}}$ in S9980 system).
$\overline{\text{INT}}1$	17	IN	Group 1, interrupt inputs. When active (low) the signal is ANDed and its corresponding mask bit and if enabled sent to the interrupt control section. INT1 has highest priority.
$\overline{\text{INT}}2$	18	IN	
$\overline{\text{INT}}3$	9	IN	
$\overline{\text{INT}}4$	8	IN	
$\overline{\text{INT}}5$	7	IN	
$\overline{\text{INT}}6$	6	IN	
$\overline{\text{INT}}7$/P15	34	I/O	Group 2, programmable interrupt (active low) or I/O pins (true logic). Each pin is individually programmable as an interrupt, an input port, or an output port.
$\overline{\text{INT}}8$/P14	33	I/O	
$\overline{\text{INT}}9$/P13	32	I/O	
$\overline{\text{INT}}10$/P12	31	I/O	
$\overline{\text{INT}}11$/P11	30	I/O	
$\overline{\text{INT}}12$/P10	29	I/O	
$\overline{\text{INT}}13$/P9	28	I/O	
$\overline{\text{INT}}14$/P8	27	I/O	
$\overline{\text{INT}}15$/P7	23	I/O	
P0	38	I/O	Group 3, I/O ports (true logic). Each pin is individually programmable as an input port or an output port.
P1	37	I/O	
P2	26	I/O	
P3	22	I/O	
P4	21	I/O	
P5	20	I/O	
P6	19	I/O

Asynchronous Communications Controller (ACC)

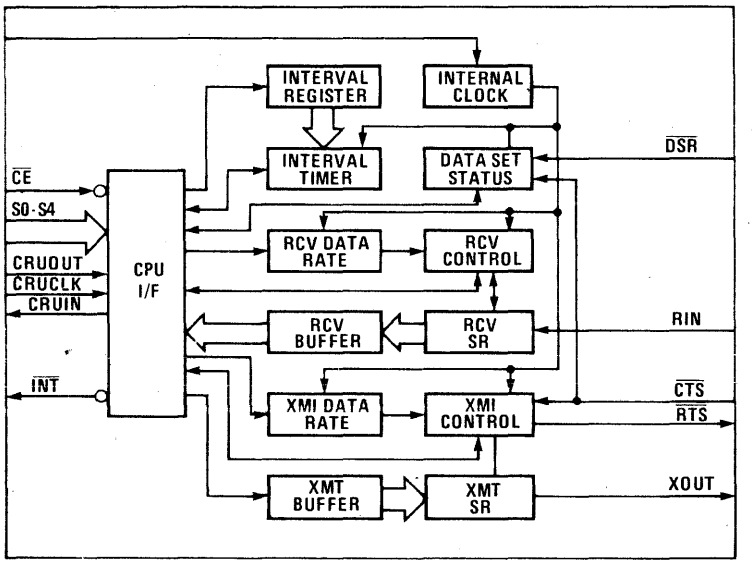
Features

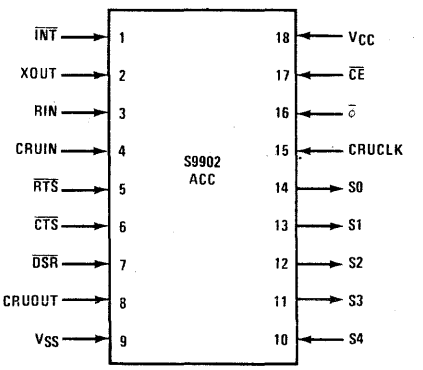
- 5- to 8-Bit Character Length
- 1, 1 1/2, or 2 Stop Bits
- Even, Odd, or No Parity
- Fully Programmable Data Rate Generation
- Interval Timer with Resolution from 64 to 16,320 μs
- Fully TTL Compatible, Including Single Power Supply.

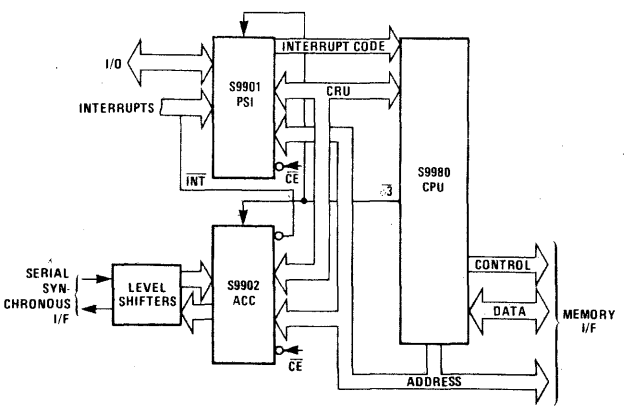
General Description

The S9902 Asynchronous Communication Controller (ACC) is a peripheral device for the S9900 family of microprocessors. The ACC provides an interface between the microprocessor and a serial asynchronous communication channel, performing the timing and data serialization and deserialization, thus facilitating the control of the asynchronous channel by the microprocessor.

Figure 1. Block Diagram







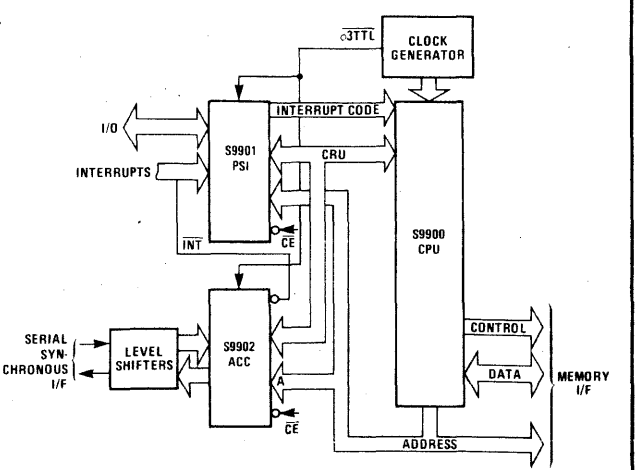


Figure 2. Pin Configuration

S9902 ACC IN A S9900 SYSTEM

S9902 Pin Description

Table 1 defines the S9902 pin assignments and describes the function of each pin as shown in Figure 2.

Table 1

Signature	Pin	I/O	Description
$\overline{INT}$	1	O	Interrupt — when active (low), the $\overline{INT}$ output indicates that at least one of the interrupt conditions has occured.
XOUT	2	O	Transmitter serial data output line — XOUT remains inactive (high) when S9902 is not transmitting.
RIN	3	I	Receiver serial data input line — RCV — must be held in the inactive (high) state when not receiving data. A transition from high to low will activate the receiver circuitry.
CRUIN	4	O	Serial data output pin from S9902 to CRUIN input pin of the CPU.
$\overline{RTS}$	5	O	Request-to-send output from S9902 to modem. This output is enabled by the CPU and remains active (low) during transmission from the S9902.
$\overline{CTS}$	6	I	Clear-to-send input from modem to S9902. When active (low), it enables the transmitter section of S9902.
$\overline{DSR}$	7	I	Data set ready input from modem to S9902. This input generates an interrupt when going On or Off.
CRUOUT	8	I	Serial data input line to S9902 from CRUOUT line of the CPU.
V_{SS}	9	I	Ground reference voltage.
S4 (LSB)	10	I	
S3	11	I	
S2	12	I	
S1	13	I	Address bus S0-S4 are the lines that are addressed by the CPU to select a particular S9902 function.
S0	14	I	
CRUCLK	15	I	CRU Clock. When active (high), S9902 from CRUOUT line of the CPU.
$\overline{\phi}$	16	I	TTL Clock.
$\overline{CE}$	17	I	Chip enable — when CE is inactive (high), the S9902 address decoding is inhibited which prevents execution of any S9902 command function. CRUIN remains at high-impedance when $\overline{CE}$ is inactive (high).
V_{CC}	18	I	Supply voltage (+5V nominal).

Device Interface

The relationship of the ACC to other components in the system is shown in Figures 4 and 5. The ACC is connected to the asychronous channel through level shifters which translate the TTL inputs and outputs to the appropriate levels (e.g., RS-232C, TTY current loop, etc.). The microprocessor transfers data to and from the ACC via the Communication Register Unit (CRU).

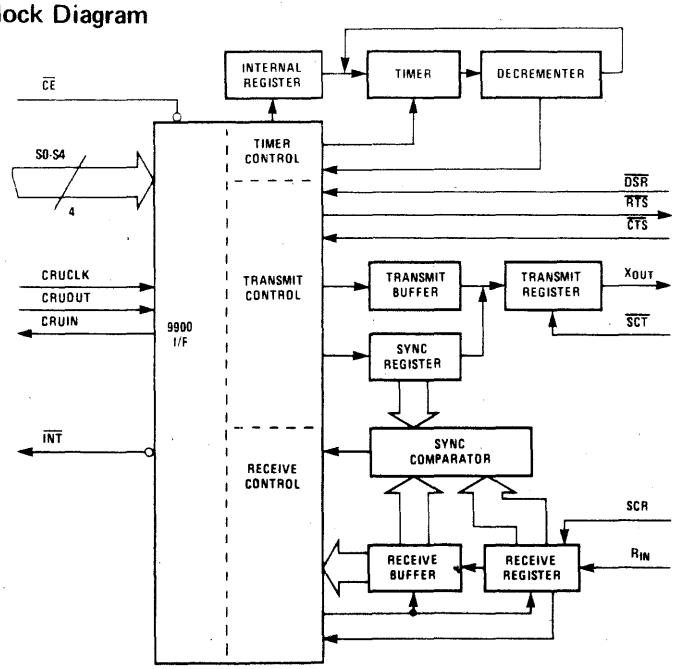
CPU Interface

The ACC interfaces to the CPU through the Communication Register Unit (CRU). The CRU interface consists of five address-select lines (S0-S4), chip enable ($\overline{CE}$), and three CRU control lines (CRUIN, CRUOUT, and CRUCLK). When $\overline{CE}$ becomes active (low), the five select lines address the CRU bit being accessed. When data is being transferred to the ACC from the CPU, CRUOUT contains the valid datum which is strobed by CRUCLK. When ACC data is being read, CRUIN is the datum output by the ACC.

©IC MASTER 1979

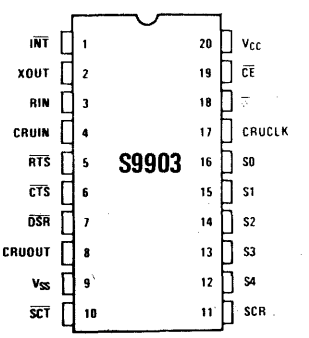
SYNCHRONOUS COMMUNICATIONS CONTROLLER

Features



- ☐ **Versatile CRU interface to synchronous and asynchronous serial devices for the S99XX series of microprocessors**
- ☐ **DC to 250 KBPS data rate, half- or full-duplex**
- ☐ **Dynamic character length selection**
- ☐ **Line protocols include BI-SYNC, SDLC, and HDLC, as well as others**
- ☐ **Programmable-polynominal CRC generation and detection**
- ☐ **Interface to unclocked or NRZI data with 32x clocks**
- ☐ **Two programmable sync registers**
- ☐ **Interval timer [64μs to 16.32ms] on chip**
- ☐ **Automatic zero insert and delete for SDLC and HDLC**
- ☐ **Single +5V supply, 20-pin DIP, all inputs and outputs TTL compatible**
- ☐ **N-channel Silicon-Gate technology**

General Description



The S9903 is a versatile device which provides the system designer with a wide range of capabilities in synchronous and asynchronous communications control. The S9903 operates in a multi-mode configuration that allows a broad range in the degree of active participation required in the control of high-speed serial communications. Most synchronous data-link control protocols can be supported through software control of sync and fill characters, timing, CRC generation and detection, etc. Established protocols such as BI-SYNC, SDLC, and HDLC are implemented directly in hardware, with others implemented through various combinations of hardware and software.

Universal applicability is further assured through the capability for dynamic character length selection from 5- to 9-bit data words plus parity. Definition and operation of all communications control is under software control and as such make upgrading to another protocol simply a matter of changing software with no hardware changes required.

S9903 PIN ASSIGNMENTS AND FUNCTIONS

SIGNATURE	PIN	I/O	DESCRIPTION
$\overline{INT}$	1	OUT	Interrupt — When active (low), the $\overline{INT}$ output indicates that at least one of the interrupt conditions has occurred.
XOUT	2	OUT	Transmitter serial data output line.
RIN	3	IN	Receiver serial data input line.
CRUIN	4	OUT	Serial Data Output line from S9903 to CRUIN input line of the CPU.
$\overline{RTS}$	5	OUT	Request to Send output from S9903 to modem. This output is enabled by the CPU and remains active (low) during data transmission from S9903.
$\overline{CTS}$	6	IN	Clear-to-send input from modem to S9903. When active (low), it enables the transmitter section of the S9903.
$\overline{DSR}$	7	IN	Data Set Ready input from modem to S9903. This input generates an interrupt when going On or Off.
CRUOUT	8	IN	Serial data input line to S9903 from CRUOUT line of the CPU.
V_{SS}	9	IN	Ground Reference Voltage
$\overline{SCT}$	10	IN	Transmit clock — Transmitter data is shifted out on one-to-zero transition of $\overline{SCT}$.
SCR	11	IN	Receiver clock — Receiver serial data (RIN) is sampled at zero-to-one transition of SCR.
S4(LSB)	12	IN	Address bus S0-S4 are the lines that are addressed by the CPU to select a particular S9903 function.
S3	13	IN	
S2	14	IN	
S1	15	IN	
S0(MSB)	16	IN	
CRUCLK	17	IN	CRU Clock. When active (high), S9903 samples the input data on CRUOUT line.
$\overline{\phi}$	18	IN	TTL Clock
$\overline{CE}$	19	IN	Chip Enable — When $\overline{CE}$ is inactive (high), the S9903 address decoding is inhibited. CRUIN remains at high impedance when $\overline{CE}$ is inactive (high).
V_{CC}	20	IN	Supply voltage (+5V nominal)

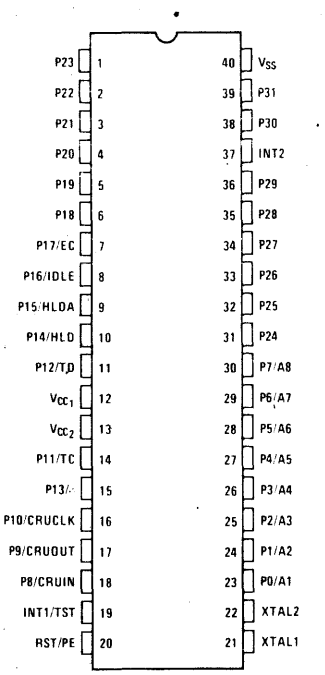
- ☐ **Single 5 Volt Power Supply**
- ☐ **Power Down Capability for Low Stand-by Power**
- ☐ **N-Channel Silicon Gate MOS**



General Description

The S9940 is a single-chip, 16-bit microcomputer containing a CPU, memory (RAM and ROM), and extensive I/O. The instruction set of the S9940 is a subset of the S9900 instruction set and includes capabilities offered by minicomputers. The unique memory-to-memory architecture features multiple register files, resident in the RAM, which allow faster response to interrupts, and increased programming flexibility. The memory consists of 128 bytes of RAM and 2048 bytes of ROM. The S9940 implements four levels of interrupts, including an internal decrementer which can be programmed as a timer or an event counter. All members of the S9900 family of peripheral circuits are compatible with the S9940.

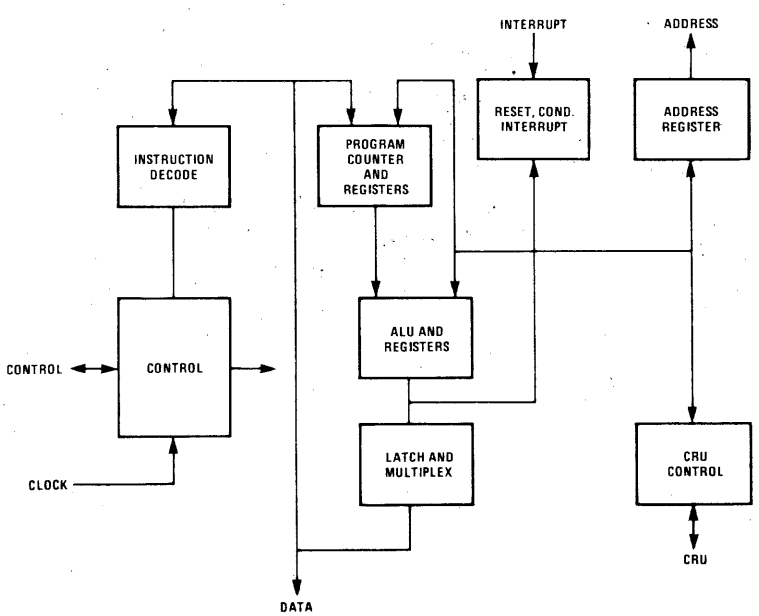
16-BIT MICROPROCESSOR

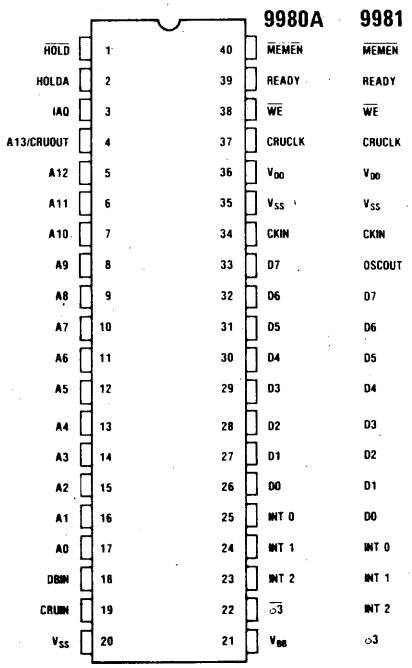
Features

- ☐ 16-Bit Instruction Word
- ☐ Full Minicomputer Instruction Set Capability Including Multiply and Divide
- ☐ Up to 16,384 Bytes of Memory
- ☐ 8-Bit Memory Data Bus
- ☐ Advanced Memory-to-Memory Architecture
- ☐ Separate Memory, I/O, and Interrupt-Bus Structures
- ☐ 16 General Registers
- ☐ 4 Prioritized Interrupts
- ☐ Programmed and DMA I/O Capability
- ☐ On-Chip 4-Phase Clock Generator
- ☐ 40-Pin Package
- ☐ N-Channel Silicon-Gate Technology



The S9980A and the S9981 although very similar, have several differences which are:

1. The S9980A requires a V_{BB} supply (pin 21) while the S9981 has an internal charge pump to generate V_{BB} from V_{CC} and V_{DD}.
2. The S9981 has an optional on-chip crystal oscillator in addition to the external clock mode of the S9980A.
3. The pin-outs are not compatible for D0-D7, INT0-INT2, and $\overline{\phi 3}$.



Description

The S9980A/S9981 is a software-compatible member of AMI's 9900 family of microprocessors. Designed to minimize the system cost for smaller systems, the S9980A/S9981 is a single-chip 16-bit central processing unit (CPU) which has an 8-bit data bus, on-chip clock, and is packaged in a 40-pin package (see Figure 1). The instruction set of the S9980A/S9981 includes the capabilities offered by full minicomputers and is exactly the same as the 9900's. The unique memory-to-memory architecture features multiple register files, resident in memory, which allow faster response to interrupts and increased programming flexibility. The separate bus structure simplifies the system design effort.

S9980A/S9981 Electrical and Mechanical Specifications

Absolute Maximum Ratings Over Operating Free-Air Temperature Range (unless otherwise noted)*

Supply voltage, V_{CC} (see Note 1) ..... – 0.3V to 15V
Supply voltage, V_{DD} (see Note 1) ..... – 0.3V to 15V
Supply voltage, V_{BB} (see Note 1) (9980A only) ..... – 5.25V to 0V
All input voltages (see Note 1) ..... – 0.3V to 15V
Output voltage (see Note 1) ..... – 2V to 7V
Continuous power dissipation ..... + 1.4W
Operating free-air temperature range ..... 0°C to 70°C
Storage temperature range ..... – 55°C to 150°C

*Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

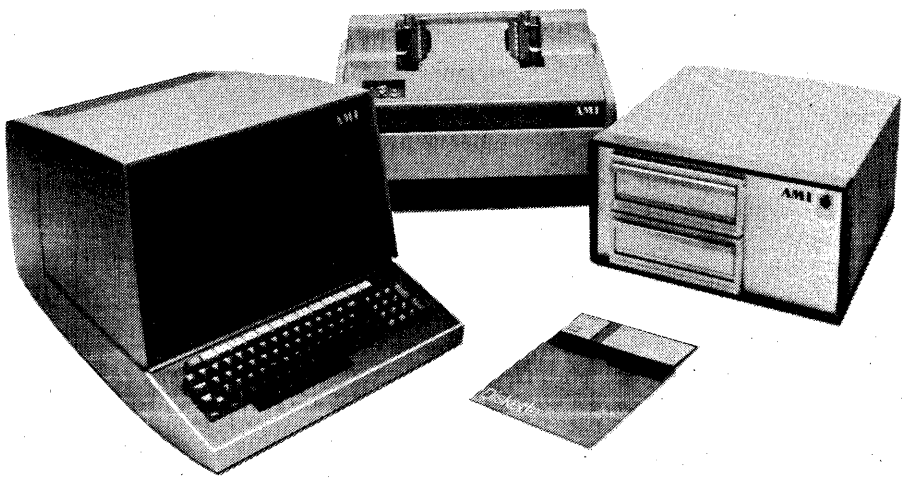
NOTE 1: Under absolute maximum ratings voltage values are with respect to V_{SS}.

Recommended Operating Conditions

Symbol	Parameter	Min.	Nom.	Max.	Unit	Conditions
V_{BB}	Supply voltage (9980A only)	– 5.25	– 5	– 4.75	V	
V_{CC}	Supply voltage	4.75	5	5.25	V	
V_{DD}	Supply voltage	11.4	12	12.6	V	
V_{SS}	Supply voltage		0		V	
V_{IH}	High-level input voltage	2.2	2.4	V_{CC} + 1	V	
V_{IL}	Low-level input voltage	– 1	0.4	0.8	V	
T_A	Operating free-air temperature	0	20	70	°C	

Electrical Characteristics Over full Range of Recommended Operating Conditions (unless otherwise noted)

Symbol	Parameter		Min.	Typ.*	Max.	Unit	Conditions
	Input current	Data bus during DBIN			± 75		$V_I = V_{SS}$ to V_{CC}
		$\overline{WE}$, $\overline{MEMEN}$, $\overline{DBIN}$ during HOLDA			± 75	μA	$V_I = V_{SS}$ to V_{CC}
		Any other inputs			± 10		
V_{OH}	High-level output voltage		2.4			V	
V_{OL}	Low-level output voltage				0.5 0.65	V	I_O = mA I_O = 3.2mA
I_{BB}	Supply current from V_{BB} (9980A only)				1	mA	
I_{CC}	Supply current from V_{CC}			50 40	60 50	mA	0°C 70°C
I_{DD}	Supply current from V_{DD}			70 65	80 75	mA	0°C 70°C
C_I	Input capacitance (any inputs except data bus)			15		pF	f = 1MHz, unmeasured pins at V_{SS}
C_{DB}	Data bus capacitance			25		pF	f = 1MHz, unmeasured pins at V_{SS}
C_O	Output capacitance (any output except data bus)			15		pF	f = 1MHz, unmeasured pins at V_{SS}



*All typical values are at T_A = 25°C and nominal voltages.

AMI Microcomputer Development Center

An intelligent stand-alone software debugging station, serving completely the combined needs of the design engineer and the programmer. It consists of a S6800 based CRT/keyboard microcomputer terminal, a dual drive floppy disk memory, and an optional hard copy printer.

A program in development (or in operation) can be viewed on the CRT and edited on the keyboard. Program files can be assembled and stored in the floppy disk memory, under control of the disk memory operating system software. The modular bus oriented card cage in the CRT terminal provides versatile facilities for developing and testing 6800 hardware.

CRT/Keyboard Terminal

- ☐ **Capability for generating 256 unique ASCII input characters**
- ☐ **12-inch diagonal CRT display — 25 lines of 80 characters**
- ☐ **16K bytes of user available RAM, expandable to 48K**
- ☐ **Full cursor and editing controls**
- ☐ **Special function controls**
- ☐ **Peripheral interconnects**

Logic Analyzer

- ☐ **General-purpose logic analyzer**
- ☐ **Plugs into MDC-100**
- ☐ **Trace memory hold 1024 steps**
- ☐ **All patterns 40 channels wide**
- ☐ **Two separate event qualifiers**
- ☐ **Data-dependent clock**
- ☐ **Outbound trigger**

Floppy Disk Memory

- ☐ **IBM 3740 data format compatible**
- ☐ **Data storage capacity of 256,256 bytes per diskette**
- ☐ **Fully supported by FDOS-II Disk Operating and File Management System software**

Optional Matrix Printer

- ☐ **132 column**
- ☐ **Dot matrix, impact printing**
- ☐ **120 or 180 characters per second**

S2000 Support

S2000 Designers can use the DEV-2000 Development Board to provide a direct link between the MDC and the user's prototype. As stand-alone systems, the S2000 designer can use the capabilities of either the low-cost SES-2000 hardware emulator — which is a pin-for-pin substitute for an S2000 microcomputer chip and contains its own EPROM memory — or the TES-S2000 functional go/no-go tester.

MDC Hardware Capabilities

The AMI MDC is a multifunction development center that single-handedly satisfies your requirements for software development, hardware development, and prototype checkout. The MDC can also double as a stand-alone communications terminal, a general purpose data processing system, or as an incoming parts tester.

Software Development — write, debug and operate S6800 and S2000 programs on the CRT terminal, using its internal RAM and the dual drive floppy disk for storage. The MDC comes with a full complement of support software, including the FDOS-II Disk Operating and File Management System, a Text Editor, an Assembler, Debugger, Trace, Telecommunications and Utilities.

Hardware Development — breadboard such cicruitry as interfaces or memories right on the MDC wirewrap prototyping board and plug into the CRT terminal card cage to operate with the MDC's S6800-based central processor in solving development problems. Use the control panel type functions of the CRT terminal for single step, stop-on-address, display, alter, and other similar program operations. The bus oriented card cage, position interchangeable plug-in card modules, and an extender card provide the flexibility to make hardware development easy. There is also a complete keyboard control led PROM programmer within the CRT terminal.

Prototype Checkout — with the advantages of a real-time test environment, rapid test program retrieval, single or multiple step execution, and hardware as well as software breakpoints, the checkout of prototype S2000 and S6800 circuitry is easy and efficient.

Stand-alone Communications Terminal — the CRT terminal has both RS-232 and current loop interfaces, supported by telecommunications firmware, for operation as a general purpose stand-alone intelligent terminal.

MDC Software Capabilities

The AMI MDC offers total facilities for rapidly developing applications and systems software. The entire MDC software system is at the user's instant disposal — a few simple keystrokes are needed to instantly access and execute any program. The FDOS-II disk based operating system provides complete system resource control to the programmer.

FDOS-II Disk Operating and File Management System — contains a resident module for bootstrapping the floppy disk memory and for disk I/O handling. It also contains an executive that performs all of the disk memory command line interpretations, file management and operational functions of the dual disk system. In addition, there are utility I/O and EPROM programming routines in FDOS-II.

The Text Editor — program provides the means for rapidly creating, examining and modifying stored files. The total capability of MDC's Text Editor exceeds that of many large minicomputer systems, and includes such features as storing searches and string substitutions.

The Symbolic Assembler — translates assembler language statements into executable machine language code. In conjunction with FDOS-II Operating and File Management Systems, assembling has been reduced to a series of simple operator keystrokes. Results of the assembly, automatically stored on disk, are immediately available for reference or execution.

MDC's Extensive Debug Program — effectively automates the functions of a computer control panel. Given control by simply pressing the DEBUG key or via program traps, Debug immediately responds with the display of machine and program status. Addition functions include:

- Register/data display and modification
- Instruction/subroutine step
- User definable debug macros
- Snapshot debug data of a running program
- Breakpoints (stop-on-address compare)
- Comment and header line displays

MDC's Trace Package — gives Debug the ability to display a trace of machine register contents, instruction mnemonics and operands before execution of any instruction or subroutine in the user's program. Microprocessor debugging has never been made easier.

MDC's Test Programs — are a set of self-test and diagnostics which verify that the hardware associated with the MDC is operating correctly. The programs are also helpful in isolating malfunctioning components. The program for testing the basic hardware is resident in EPROM and is activated by the keyboard TEST key.

©IC MASTER 1979

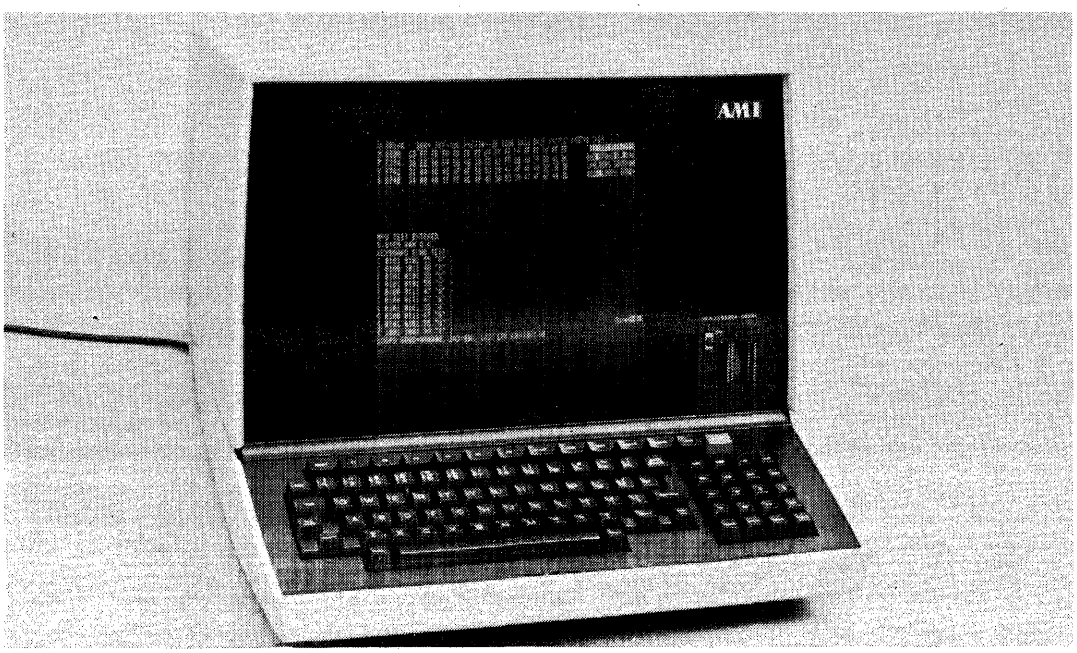
Microcomputer Development Center

Features

- ☐ Intelligent Terminal Based
- ☐ Compact System
- ☐ Interactive Software
- ☐ S6800/S2000 Family
- ☐ Self-Test Firmware
- ☐ Integral PROM Programming

The AMI MDC is a complete Microcomputer Development Center which couples the ease of use of the intelligent terminal with the modularity required in today's environment. The system provides immediate access to a sophisticated resident Micromonitor, an extensive debug program, as well as communications and self-test programs.

MDC 100



This configuration of AMI's Microcomputer system incorporates the intelligent terminal and dual floppy disk drives to form a full development center for software and hardware development and prototype check-out. The powerful support software includes the FDOSII Disk Operating and File Management System, a Text Editor, an Assembler, Debugger, Trace, Telecommunications and Utilities. Through the Operating System, the MDC 100 can be quickly configured to assemble and/or compile and debug programs for AMI's S6800 or S2000 Families of microprocessors. An integral EPROM Programmer allows the MDC System to be used to quickly and efficiently transfer programs from the expandible RAM Storage (16K supplied) to permanent storage.

MDC 102

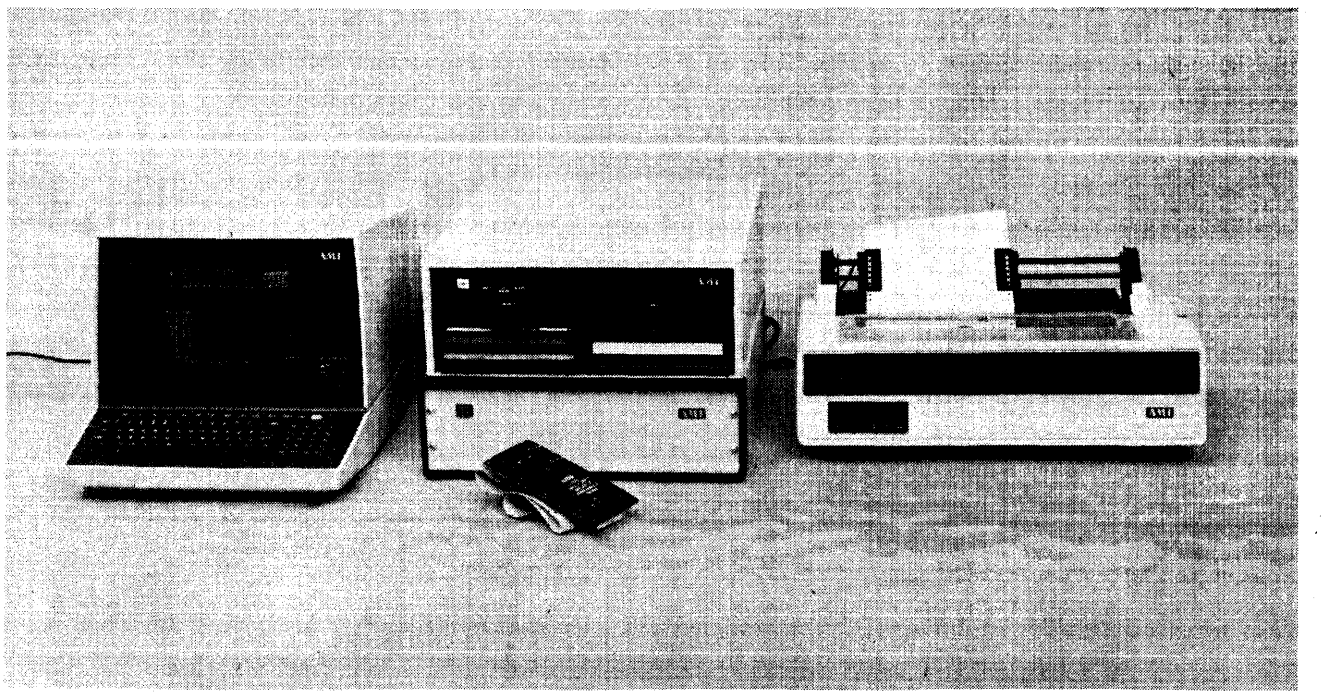
The MDC 102 couples the MDC 100 with a highly efficient Dot Matrix printer to provide the hard copy necessary for off-line program evaluation. The printer is the MDC 202, one of three printer options offered in the MDC Series. The MDC 202 features 120cps print speed with 132 character print columns using a 7 x 7 Dot Matrix.

MDC 104

The MDC 104 is an AMI Microcomputer Development Center configuration which adds the powerful prototyping tool of the Logic Analyzer to the development capabilities of the MDC 100. The Analyzer is indispensable when isolating critical timing errors and hardware/software sequence discrepancies during the final integration phases of prototype development.

©IC MASTER 1979

The MDC Logic Analyzer is a hardware/software system for capturing and displaying up to 40 parallel signals from an external digital system which is being tested or debugged. The MDC Logic Analyzer is especially general in its display formatting which can be user-defined. With 40 signal inputs plus a clock, it can be used with most microprocessor and peripheral ICs without requiring personality modules.

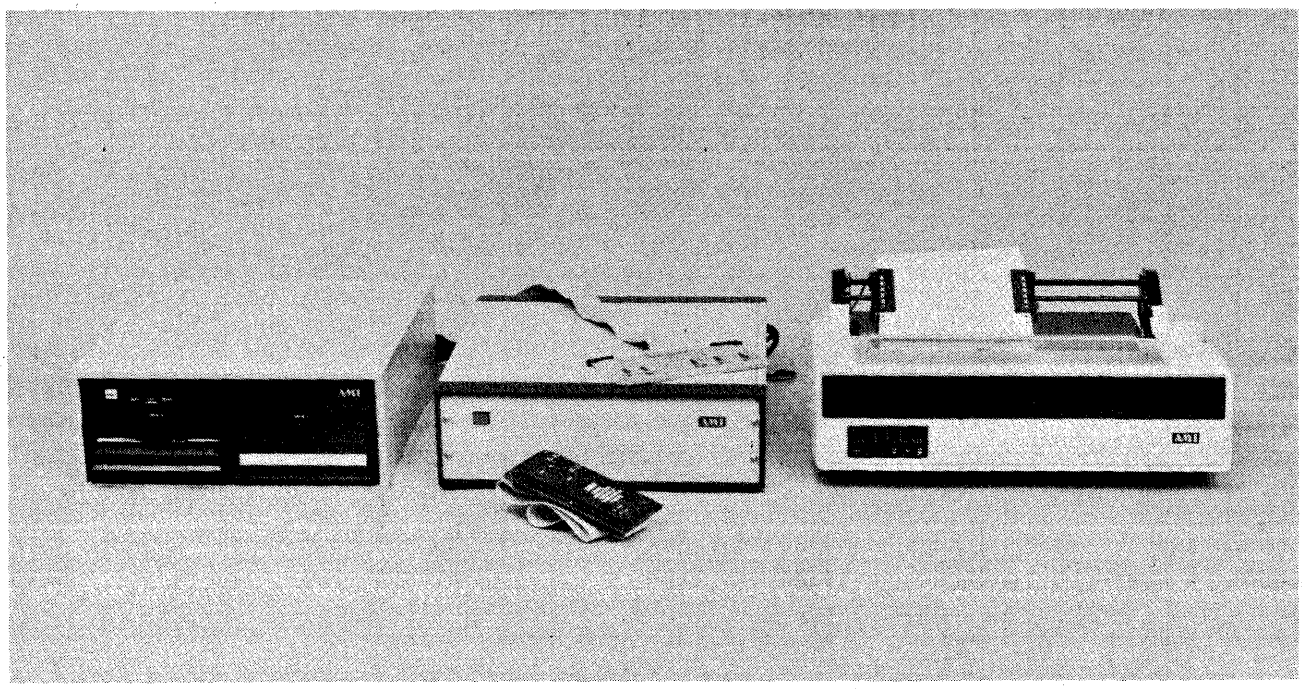


The hardware of the Logic Analyzer allows capturing up to 1024 events of 40 parallel inputs, programmable data-dependent start and clock signals, and a trigger for an external oscilloscope or counter. The two starting qualifiers, the dependent clock, and the trigger may each consist of the 40 input signals in any combination of 1, 0, or "don't care" states.

The end of the capturing process may be delayed up to 65K clock pulses from the start. User inputs may be from -15 to +15 volts with adjustable thresholds at frequencies up to 10MHz for TTL signals.

The software package provided links the capabilities of the MDC 100 and the Logic Analyzer. It provides completely user-defined formatting and display of captured data and data-dependent qualifiers with user-defined fields displayed in binary, hexadecimal, octal, ASCII, or user-defined signal names. A special disassembly mode is available for 6800/6802 instruction mnemonics and operands.

Formats may be saved on and read from floppy disk files and modified dynamically. A set of pre-defined formats are provided for use with the pinouts of the S6800 microprocessor family and S2000 microcomputer.



The Logic Analyzer consists of trace RAM, control logic, power supply, an interface card for the MDC, a comparator/probe control card, user clock and trigger leads, 40 channels of probes (separately or in one clip) and interconnecting cables. The unit is available as an optional item to be added to existing systems as the MDC 140.

©IC MASTER 1979

MDC 106

As an all inclusive Development Center the MDC 106 offers total design support. The powerful MDC 100 system with a Dot Matrix printer and the Logic Analyzer provide a complete development package for integrating software and hardware. The MDC 106 offers the tools necessary to move rapidly through software development and debug to full hardware analysis and debug for rapid development of microcomputer-based products.

SES SERIES

STATIC EMULATOR MODULES

Features

- ☐ Full Microcomputer Emulation
- ☐ Erasable Program Memory
- ☐ Fully-Tested Operational System
- ☐ System Socket Compatible

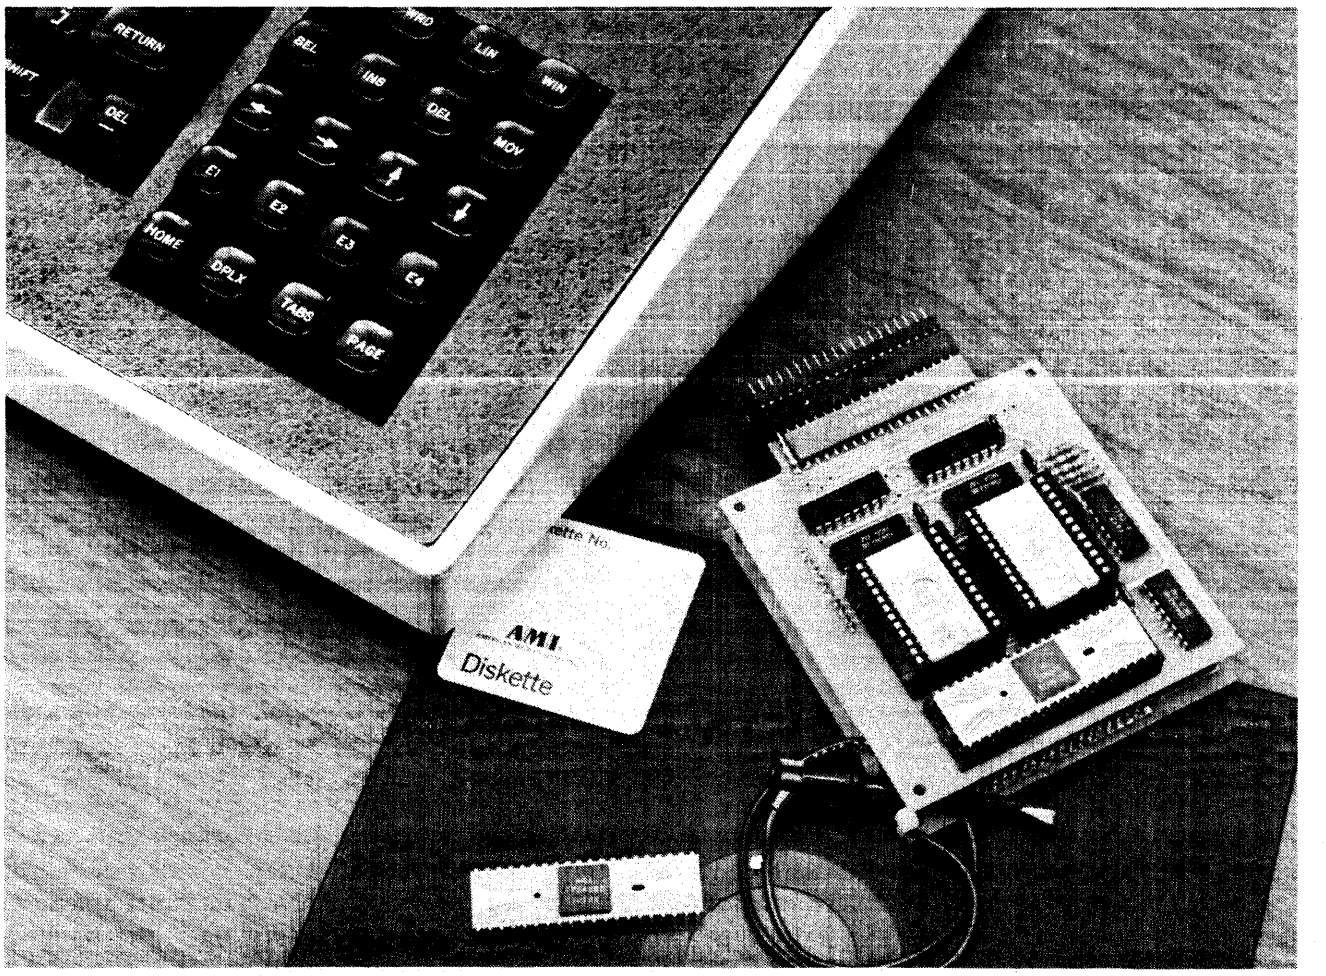
The SES Series of boards provide pin-for-pin emulation of single-chip microcomputers. The board offers the full operational capabilities of the single-chip microcomputer coupled with the flexibility of board level design. The Series incorporates on-board Erasable PROM to provide ease of program modification in prototype environment.

SES 2000/2000A

The SES 2000 is an emulator board for the popular S2000 single-chip microcomputer. This board level unit is configured to plug directly into the system socket that would normally hold the mask programmed S2000. Through the use of the SES 2000, system hardware and program configurations can be quickly and efficiently accomplished in the prototype stages. The board is also suited for integration into preproduction systems allowing full freedom of modification through memory changes in standard EPROMs. For systems utilizing the S2000A, which is capable of driving high voltage vacuum fluorescent displays, the SES 2000A provides the system emulation of the S2000A. Program implementation and functional operation is the same as that found in the SES 2000.

©IC MASTER 1979

SES 2150/2150A



The SES 2150 provides full emulation for the S2150. This system unit incorporates an expanded EPROM on-board to match the 1.5K byte ROM memory capabilities of the single-chip microcomputer.

The SES 2150A broad level system allows the implementation and emulation of the high voltage version of the S2150 and the S2150A. All the features of the SES 2000 series are offered in this unit to assist in prototype and preproduction development.

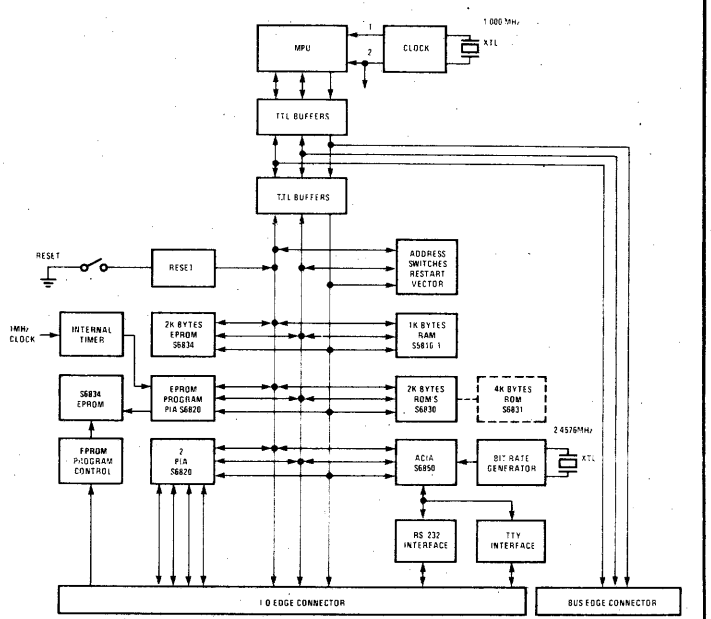
SES 2400/2400A

An advanced emulator board capable of emulating the functions of the S2200 and the S2400 single-chip microcomputers. Full functional capabilities are provided including D/A and A/D input/output functions. On-board EPROM provides a full compliment of user-modifiable program memory.

The SES 2400A emulator board provides the high voltage interface necessary to emulate the S2200A and the S2400A single-chip microcomputers.

©IC MASTER 1979

MICROCOMPUTER BOARDS/KITS



Features

- ☐ **Expandable to 4K Bytes ROM**
- ☐ **Expandable to 2K Bytes EPROM**
- ☐ **Expandble to 1K Bytes RAM**
- ☐ **EPROM Programming for S6834**
- ☐ **Expandable to 3 PIA's = 58 I/O Lines**
- ☐ **TTY Current Loop or RS232 Interface**
- ☐ **ROM Subroutine Program Library**
- ☐ **Selectable DMA Mode**

General Description

The EVK Series Board is a single PCB, hardware/software system that can be used as a general purpose microcomputer. It allows system development using a functionally compatible system and reduced development time. With this system the basic 6800 family of parts can also be evaluated. The 10-1/2"x12" card has two edge connectors, one for the MPU Bus and one for the I/O. The EVK 300 is a fully assembled and tested board, while the EVK 200, EVK 100 and EVK 99 are in kit form. All kits are fully expandable to EVK 300 capabilities.

– A high level interpretive language derived from the standard Dartmouth BASIC. Furnished to EVK 300 users at no charge upon submittal of warranty registration.

ADVANCED PRODUCT DESCRIPTION

©IC MASTER 1979

System Specifications

All of the S6800 microprocessor lines are available at the bus edge connector and are buffered to allow 40mA of drive capacity for expanding the development system. The standard system clock is adjustable from 300kHz to 1MHz by using the potentiometers on the board. An optional 1MHz crystal may be selected to control the accuracy for those applications requiring critical timings.

An on-board interval timer gives 1ms and 100μs timing marks for general use and for EPROM programming. Three types of DMA operation are possible using the EVK Board: Halt Processor, Cycle Steal or Multiplexing.

Memory

Memory and I/O addresses are assigned to the upper 8K bytes of the available memory space. (See memory map for address assignments.) This gives the system developer the flexibility to use the remaining 56K bytes as he wishes. All of the memory and I/O on the board may be disabled externally by an edge connector line called MEMORY DISABLE, leaving the MPU free to operate totally in an external memory.

The S6830 ROMs contain the Prototype Operating Library (PROTO) and a ROM Subroutine Library $(RS)^3$. An optional Assembler/Disassembler (M/AD) S6831 ROM is available to operate with PROTO. The 2K of EPROM locations may also be used for program verification.

The RAM is assigned to the upper 1K of available memory space. The PROTO and $(RS)^3$ programs require about 256 bytes of this RAM so the rest is available for general programming. With all restart vectors automatically assigned to the upper memory addresses, restart vectoring is forced from a set of 16 switches. This allows the restart address to be vectored to any memory location.

The RAM has further been divided into two 512 byte sections such that the upper 512 bytes remain fixed in the assigned address block and the lower 512 bytes are moveable through a switch selection option. 512 bytes of RAM are relocatable to the lowest address space to take advantage of the S6800's direct addressing mode. This is only recommended if no external memory is added. When adding external memory, it is advisable to use the RAM in the upper address space and the external memory as the low addresses.

I/O

An S6850 ACIA is used to provide a 20mA current loop interface to a TTY or RS232 terminal. A 20mA current loop interface and an EIA RS232 interface are both available on the board. A bit rate generator allows operation using any of the standard communication frequencies (see table) so a large variety of terminal types can be used.

Three S6820 PIAs allow up to 58 I/O lines, giving flexibility in I/O through the parallel interfaces.

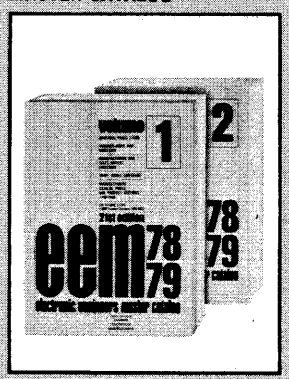
EPROM Programming

Unique to the AMI EVK Board is the ability to program S6834 EPROMs (512 x 8) on the board. The programming software can program an EPROM from any memory location, RAM, ROM or EPROM. It can verify a word and, if desired, change a single bit in the EPROM, provided that the change is from LOW to HIGH.

Software

The EVK Board Software is comprised of a TTY Operating Program (PROTO) and is supported by a ROM Subroutine Library $(RS)^3$.

Specifications



Power	+5VDC @ 3.5A
with EPROMs	−12VDC @ 150mA
System Clock	1MHz ±.1%
Word Size	
Instruction	8, 16 or 24 bits
Data	8 bits

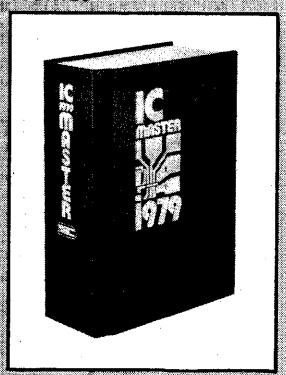
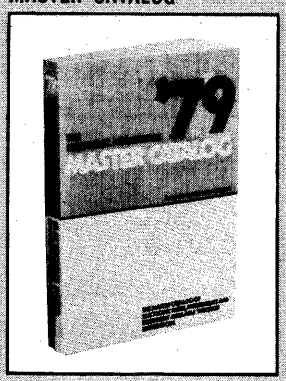
WE KNOW OUR STUFF



42 YEARS OF EXPERIENCE IN CATALOGING, 22 EDITIONS OF eem

eem/ELECTRONIC ENGINEERS MASTER CATALOG —



The "blue-ribbon" catalog/directory that has become "the standard of the industry" for electronic engineers, buyers and specifiers.

IC MASTER AND THE UPDATES —

The only complete single-source directory including all IC devices manufactured in the United States. Updated three times yearly with accumulative supplements.

ELECTRONIC DISTRIBUTORS MASTER CATALOG —

The only national catalog designed exclusively for distributors and their customers featuring electronic parts, instruments and equipment.

ELECTRONIC PRODUCTS MAGAZINE —

The products magazine . . . A 100% product-oriented magazine including hundreds of new products and special features every month.

eem FILE SYSTEM —

The only filing system designed especially for the electronics engineer. Instant retrieval and organization of data sheets and catalogs.

UTP CUSTOM CATALOGS —

The Cadillac of individualized catalogs for the electronic parts distributor, featuring solely his lines and services.

UNITED COST AND PRICING SERVICES —

The electronic distributors' proven method of being up to the minute on his cost and selling prices.

F8/3870 • F6800 • 9440
MICROFLAME BIT SLICE

FAIRCHILD MICROCOMPUTERS

Fairchild microcomputers cover the spectrum from 8-bit MOS microprocessors to bit-slices and 16-bit bipolar machines.

- 1-Chip F3870 MicroMachine-2™/the multichip F8 family with software and compatibility.
- 2-Chip F6802/6846 combination plus a powerful bus oriented F6800 family well supported by a large variety of peripheral devices.
- Three high-performance bipolar bit-slice families:
  Macrologic
  2900
  8-bit ECL (90LSI)
- 16-bit bipolar 9440 Microflame™ microprocessor that brings minicomputer capabilities to the microprocessor world.

These products are supported by training courses for the design engineer who must learn to design the microprocessor into a working system and for those designers who need to complement their hardware capabilities with software (instruction set) or those software types who must gain an intimate knowledge of the hardware. All courses emphasize lots of hand-on time backed by examples to enhance students' working familiarity with each microprocessor.

Courses are offered at Mountain View, California or on site courses may be arranged with a local Farchild sales office or distributor.

HOW TO ENROLL — Call or write the Training Center at (415) 962-3710, M/S 20-1028.

FAIRCHILD F3870 — The 8-bit single chip F3870 Microcomputer is ideal for high volume, low cost applications, featuring a single +5V power supply, 2048 bytes of ROM, 64 bytes of scratchpad RAM, 32-bits of I/O, and a programmable timer and interrupt.

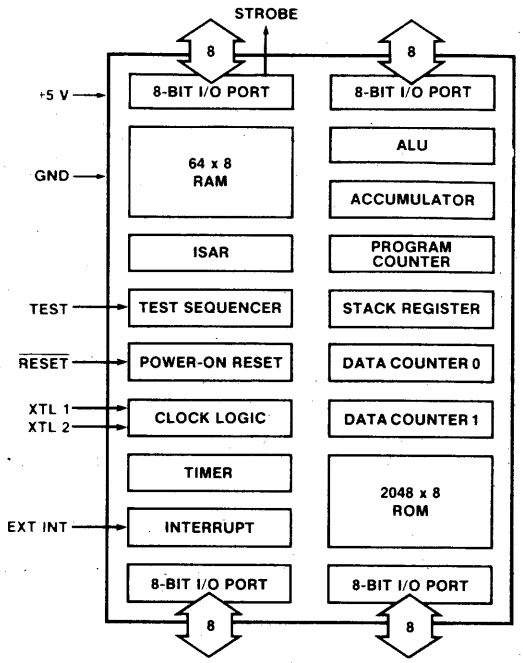
FAIRCHILD F6800 — The 8-bit MOS F6800 family offers a complete and continuously expanding range of microprocessor devices with a powerful instruction set. On the low end there is the F6802/6846 2-chip combination that features a processor chip combination with 128 bytes of on board RAM of which 32 bytes have a power down feature.

The F6800 family is supported by a large array of pheripheral devices which include: ROM, RAM, EPROM, Synchronous and Asynchronous Controller for date communications, Timers, Direct Memory Access (DMA), CRT Controller, the 68488 for the IEEE Standard Bus Controller.

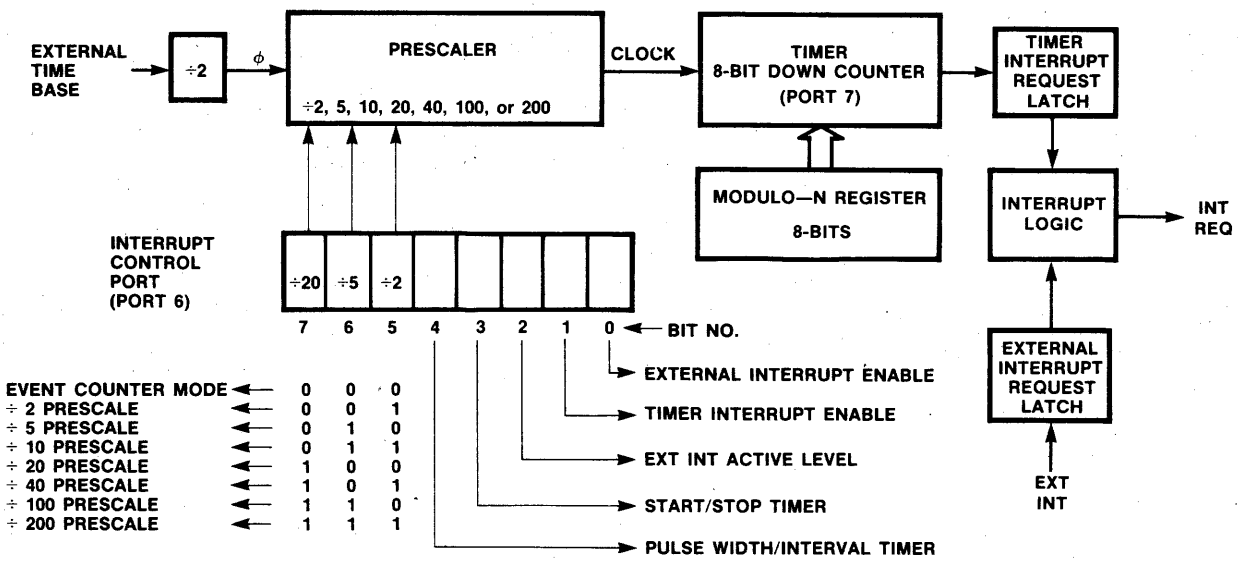
FAIRCHILD BIT-SLICES — In 1975, Fairchild announced the Macrologic bipolar bit-slice microprocessor family. To broaden our product lines and strengthen our leadership position in 1978 Fairchild added the 2900 family. In addition and to satisfy the ultimate requirement in performance, we are introducing an 8-bit ECL F100K compatible microprocessor family (90LSI). The Fairchild bit-slice course will cover basic microprogramming concepts and techniques, survey the three most powerful bipolar bit-slice families — Macrologic, 2900, and 90LSI — and offer the student some hands-on experience.

FAIRCHILD 9440 MICROFLAME — The 9440 MICROFLAME is a 16-bit bipolar microprocessor that executes a minicomputer multifunction instruction set with minicomputing performance — e.g., fast throughput, flexible addressing, direct memory access and sophisticated priority interrupt handling. The development of the MICROFLAME microprocessor was undertaken several years ago after the establishment of the high-performance I^3L (Isoplanar Integrated Injection Logic) technology. For the first time, the potential for real bipolar performances (less than 10ns propagation delays) in LSI configurations became a reality. Also, it was soon apparent that a 10 MHz clock-rate microprocessor could be developed using I^3L technology in combination with proven logic and circuit design. Thus, the decision was made to develop a microprocessor that would bring minicomputer capabilities to the microprocessor world.

FAIRCHILD



©IC MASTER 1979



F3870 FAMILY

F3870 — These devices are complete 8-bit microcomputers on single MOS integrated circuits. The family can execute the F8 instruction set of more than 70 commands, allowing expansion into multi-chip configurations with software compatibility. The devices feature read only memory, 64 bytes of scratchpad RAM, a programmable binary timer, 32 bits of I/O, and a single +5 V power supply requirement.

Members of the family differ in memory type and size. The F3870 has 2048 bytes of mask programmed ROM while the F38E70 has 2048 bytes of PROM. The 3872 has 4032 bytes of masked ROM plus 64 bytes of RAM. The additional RAM is addressed from the program and data counters, not the ISAR. The F3874 contains 4096 bytes of masked programmed ROM.

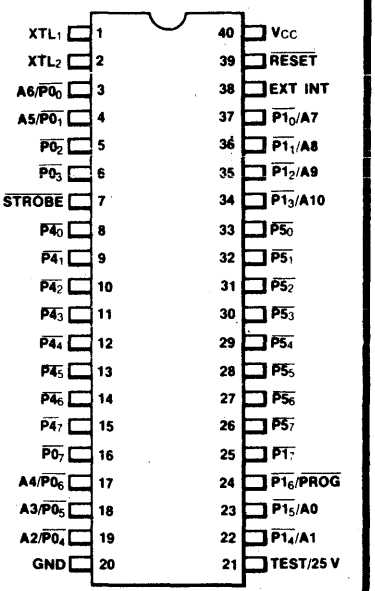
Utilizing ion-implanted, n-channel silicon-gate technology and advanced circuit design techniques, Fairchild's single-chip microcomputers offer maximum cost effectiveness in a wide range of control and logic replacement applications.

TIMER AND INTERRUPT CONTROL FOR F3870

©IC MASTER 1979

F38E70

SINGLE-CHIP COMPUTER



FAIRCHILD MICROCOMPUTER FAMILY

GENERAL DESCRIPTION–The Fairchild single-chip microcomputer series offers a variety of circuits for the high-volume, cost-sensitive markets. The F38E70 is a complete 8-bit microcomputer on a single MOS integrated circuit. The F38E70 is functionally identical to the F3870 except the F38E70 has 2K bytes of EPROM in place of 2K bytes of ROM. The F38E70 can execute the F8 instruction set of more than 70 commands. The device features 2048 bytes of EPROM, 64 bytes of scratch-pad RAM, a programmable binary timer, 32 bits of I/O, and a single +5 V power supply requirement.

Utilizing Fairchild's double-ion-implant, n-channel technology and advanced circuit design techniques, the single-chip F38E70 offers maximum cost effectiveness in many low-to-medium volume systems. When production volume requires large quantities, the transition to the mask programmed F3870 is very straightforward with no circuit design changes.

- **SINGLE-CHIP MICROCOMPUTER**
- **SOFTWARE COMPATIBLE WITH F8 FAMILY**
- **2048-BYTE EPROM**
- **64-BYTE SCRATCHPAD RAM**
- **32-BITS (FOUR PORTS) TTL COMPATIBLE I/O**
- **PROGRAMMABLE BINARY TIMER**
  - **INTERVAL TIMER MODE**
  - **PULSE WIDTH MEASUREMENT MODE**
  - **EVENT COUNTER MODE**
- **EXTERNAL INTERRUPT**
- **CRYSTAL, LC, RC, EXTERNAL, OR INTERNAL TIME BASE**
- **LOW POWER (375 mW TYP)**
- **SINGLE +5 V ±10% POWER SUPPLY**
- **+25 V PROGRAMMING SUPPLY**
- **SIMPLE EPROM PROGRAMMING**

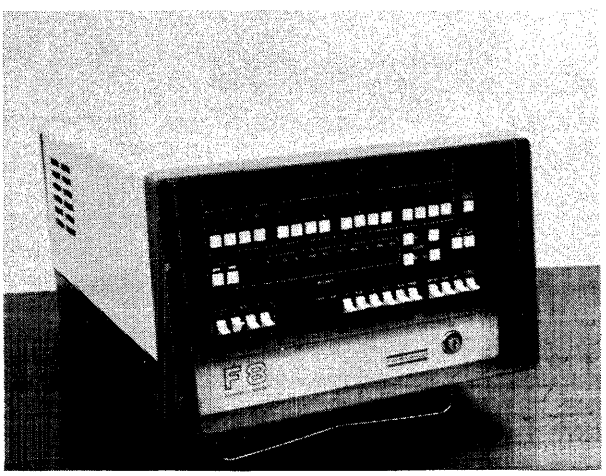
F3870 DEVELOPMENT SUPPORT — The Formulator family of develpment equipment supports the F3870, the one-chip micromachine manufactured by Fairchild. The Formulator Operating System, Utility Programs, and the Fairbug Monitor are totally compatible with the F3870, since it shares the same instruction set with the Formulator. A Simulation (Quad I/O) Module and an In-Circuit Emulation (ICE) cable are available to extend the Formulator features to the user's prototype or production breadboard. This creates a powerful design tool for creating the user's own F3870 software. In addition, the F3870 Emulator, a single stand-alone module for emulating the final F3870 software in PROMs, is available for building prototype systems.

F3870 SIMULATION — The non-microprocessor elements of the user's hardware configuration can be assembled on a breadboard and connected to Mark I, II, IIFD, III or IIIFD via the ICE cable plugged into a 40-pin socket on the user's board. The cable connector on the Processor Module in the Formulator provides I/O ports 0 and 1, while the Simulation (Quad I/O) Module provides I/O ports 4 and 5. This system provides real-world simulation of the user's components in their actual environment with the vital microprocessor signals, including the complete software debugging features of the Formulator, cabled to the external breadboard.



F3870 EMULATOR — After F3870 ROM codes are frozen, a smaller, easier-to-handle and less expensive tool is required. To accomplish this design-in task, Fairchild has developed the F3870 Emulator. The F3870 Emulator contains sockets for two 2708s or two 2716 EROMs in place of the F3870 on-chip ROM so ROM codes can be verified and easily changed. The F3870 Emulator plugs directly into the F3870 40-pin socket in the production prototype using a short Emulator cable. The printed circuit module is approximately 5" by 7".

The F387X PEP System Hardware Features

- Full In-Circuit Emulation of F3870, F3874 and F3876 Single Chip Microprocessors Using the Fairchild F8 System. (Emulation Cable Included.)
- Includes a 2K Firmware Monitor in an F8 PSU.
- Versatile On-Card Keyboard for Command and Data Entry.
- On-card 7-Segment Address and Data Display Using Large .8" Digits
- Programming Socket for the F38E70 Single Chip EPROM Microprocessor.
- Programming Socket for 2716 EPROMs.
- Crystal Controlled System Clocks.
- 2K Bytes of Executable Static RAM (2114s).
- Sockets for an Additional 2K Bytes of Static RAM (2114s).
- Sockets for 6K of Executable EPROM (2716 Type).
- Separate 128 Byte Static Memory for Monitor Workspace.
- Flexible Memory Map Strapping Options.
- Serial I/O Circuits for TTY 20 mA Current Loop or EIA RS232C.
- Four General Purpose Programmable Timers.
- Four General Purpose Interrupt Controls.
- Spare 8-Bit I/O Port for Support of a High Speed Paper Tape Reader.
- LED Indication of "Store Mode" Keyboard Operation.
- LED Indication of "Function Shift Mode" Keyboard Operation.

THE FAIRCHILD F387X PEP SYSTEM

©IC MASTER 1979

F3870 — The following is the text of an article that will be printed in *Progress*. It may have information that you would find valuable.

F3870 DESIGN INNOVATION — The F3870 is Fairchild's new single chip microcomputer. The F3870 has on a single chip all of the basic computer components including memory, central processing unit and input/output. F3870 includes:

2048 x 8 ROM
64 x 8 RAM
32 bits TTL compatible I/O including strobe
Programmable Binary Timer with three modes
Two-level prioritized vectored interrupts
Five clock modes
Single 5 V + 10% Power Supply
275 mW power consumption

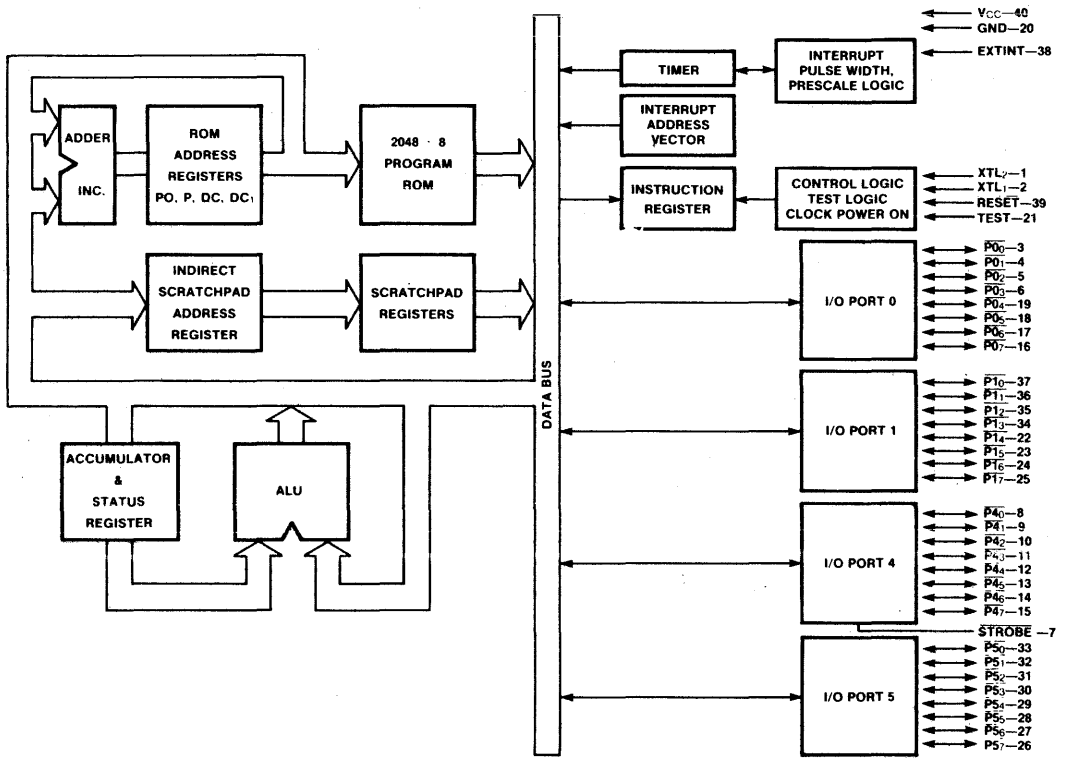
The circuit is fabricated with Fairchild's advanced triple implant n-channel silicon technology.

Figure 1 shows the architectural organization of the F3870. Notice that all communication with the outside world is through I/O ports and the interrupt line since the data and address busses are not brought out in the 40 pin package.

There are several attributes that make the F3870 a unique and powerful single-chip computer. Figure 2 illustrates the I/O logic for one-bit.

The I/O ports are designed to be inherently bidirectional. In the standard I/O circuit shown, the input or output function is determined by the instruction executed. An output instruction will latch the data and either pull down the I/O pin to ground or let it be pulled up to +5V through the 6 resistor. The data input is the wired OR of the output state and the input on the I/O pin. Therefore, to perform an input function, a "0" is written to the output latch, allowing the I/O pin to be pulled up to V_{CC} through the 6 k resistor. The input to the I/O pin can then pull down the I/O line through the 6 k resistor to input a "1" to selected bits in I/O port latch, a masking operation is performed on the input data by pulling the output bit low preventing input on the selected bits. The I/O logic is very nice for bus oriented systems since I/O ports can also be tied to open collector TTL outputs as pull down devices. However, an I/O port should never be pulled up, since the rating of the output device will be exceeded and the chip will be destroyed.

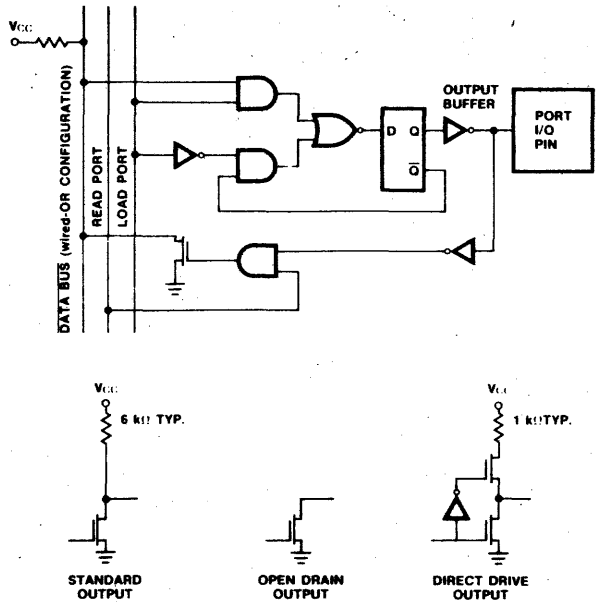
Figure 3 illustrates how multiple F3870's can be connected along a common communication bus bia the bidirectional ports. In the system shown, the control and timing busses are used to communicate priority and bus control information between three processors. When one processor is selected as the control processor, the other F3870's write "0" to their ports on the communication bus. The processor in control can then output information on to the communication bus and the devices can read. Timing to initiate the transfer is via the timing bus and another I/O port. Transfer can also be initiated using the output strobe line and the interrupt logic.



A UNIQUE ROM DESIGN — Probably the most important attribute of the F3870 is the low cost. The low selling price is direct relation to the manufacturing cost. In the production of LSI circuits manufacturing costs is a very strong function of chip size. The smaller the size of the chip, the more possible good chips on a wafer. The F3870 is the smallest full performance 8-bit single chip microcomputer in the world. The die size is 172 mills by 208 mills. To a large extent the small die size is due to the very efficient ROM design. The new ROM technique is shown in Figure 4. Figure 4 shows eight ROM bits. Information is programmed at the factory by a ION implant stage rather than a conventional gate oxide cut. To read a bit, the column select transistor is turned on and the row select logic turns on all the devices in a column except the one to be read. The logic attempts to turn off the one being read. If the transistor has been implanted it cannot be turned off and read as a one. The layout of the ROM is shown in Figure 5. Notice that adjacent bits share a common source and drain diffusion. Also notice that no contacts are required to the diffusions except for the top and bottom devices in a column. A single bit cell area is indicated by the shaded regions for F3870, the area is approximately 100 square microns. This compares with conventional ROMs cell area of approximately 196 square microns. The almost two to one savings in area is reason that the F3870 has twice as much ROM as most of its competitors.

THE REGULATED BACK BIAS GENERATOR — The diagram for a conventional MOS transistor is shown in Figure 6. A back bias voltage is often applied to the substrate to speed up the device and change its threshold. Back bias supplies are commonly found in high-speed RAMs. For single 5 V supply devices no back bias is used, and most single supply parts are therefore lower performance. To alleviate the problem of single power supply performance the F3870 uses a regulated on chip

back bias power supply. A simplified diagram of this supply drawn in Figure 7. A 1 MHz oscillator generates the two phases required by the power supply. A switch turns the oscillator on or off as needed to maintain the correct amount of back bias voltage for maximum circuit performance. The circuit operates by charging up the capacitors and transferring charge through the diodes.



The regulator of the oscillator has other benefits besides improving the speed of the F3870, the regulator also makes the device able to work with a power supply spec of ±10%. Also, the regulator tends to track with temperature making extended temperature operation easier to achieve. And finally, the regulator follows process changes and aging in the circuit resulting in a chip that is lower cost to build and has enhanced long term reliability.

COST AND PERFORMANCE — The reasons that the F3870 is the dominant force in single chip microcomputers are cost and performance. The architecture and logic is designed for very high performance. The addressing modes available enable very compact programs with high-speed execution. The strobe, I/O port, and interrupt logic allows high-speed hand shaking and data transfer through the bidirectional I/O ports, to make all of the high performance features cost effective, create ROM design and the on chip regulated back bias supply are used. The F3870 has all the attributes required of a successful microcomputer — low cost, high performance, excellent support and multiple sourcing.

PIN NAME	TYPE	DESCRIPTION
$\overline{P0_0}$-$\overline{P0_7}$ $\overline{P1_0}$-$\overline{P1_7}$ $\overline{P4_0}$-$\overline{P4_7}$ $\overline{P5_0}$-$\overline{P5_7}$	INPUT/OUTPUT	32 lines which can be individually used as either TTL compatible inputs or as latched outputs.
$\overline{STROBE}$	OUTPUT	This pin, which is normally HIGH, provides a single LOW pulse after valid data is present on the $\overline{P4_0}$-$\overline{P4_7}$ pins during an output instruction.
$\overline{RESET}$	INPUT	$\overline{RESET}$ may be used to externally reset the F3870. When pulled LOW the F3870 will reset. When then allowed to go HIGH the F3870 will begin program execution at the program location H '0000'.

©IC MASTER 1979

Ports 0 And 1 Are Standard Output Type Only

Ports 4 And 5 May Both Be Any Of The Three Output Options

The STROBE Output Is Always Configured Similar To A Standard Output Except That It Is Capable Of Driving Three TTL Loads

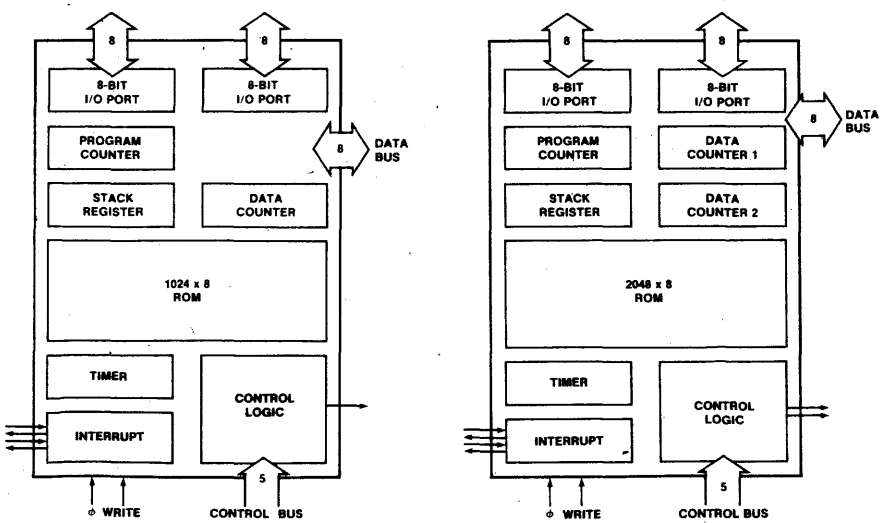
3850 Central Processing Unit (CPU)

Fairchild's F8 CPU contains all of the functions needed to provide the most inexpensive solution to your design problems. The 3850 has 64 bytes of RAM, 16 bits of bidirectional I/O and a complete set of easy to understand instructions with both binary and decimal arithmetic operations.



3850
CPU BLOCK DIAGRAM

3851/3856/38T56* Program Storage Units (PSUs)

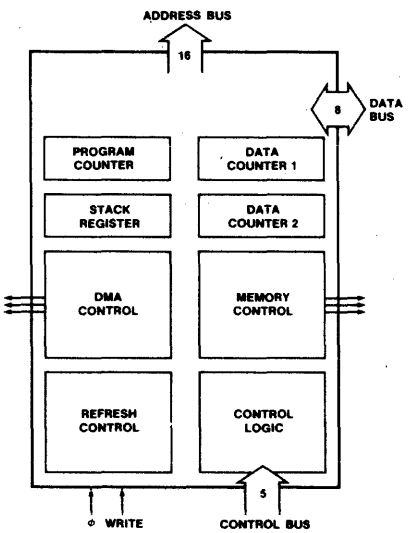
The 3851 PSU contains 1K of program storage and the 3856 2K. Both provide 16 bits of bidirectional I/O, a timer and external interrupt and a vectorized, prioritized interrupt structure. Additional PSUs may be added as required and I/O expansion naturally follows.

*Uses special timer, see page

3851 3856

PSU BLOCK DIAGRAM

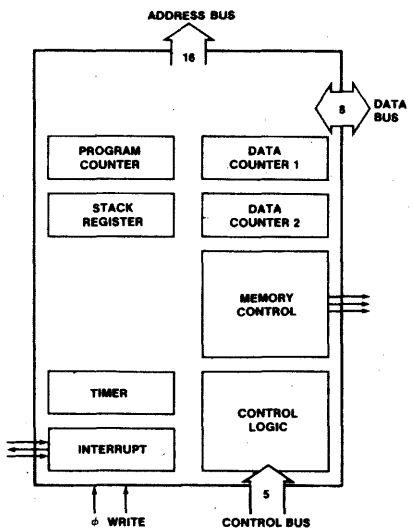
©IC MASTER 1979



3852/3853/3857/38T57* Memory Interface Circuits

Additional memory can be easily added to the system by using any of the three Memory Interface Circuits. Each device generates the 16 address lines and signals necessary to interface with up to 65K bytes of RAM, PROM or ROM memory and they all may be used in conjunction with any standard semiconductor memory device.

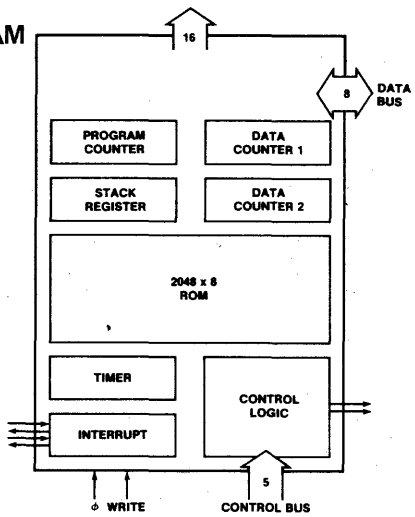
The 3852 Dynamic Memory Interface (DMI) provides memory refresh and DMA logic which run transparent to the CPU without any degradation in the system throughput time.



*Uses special timer, see page

3852
DMI BLOCK DIAGRAM

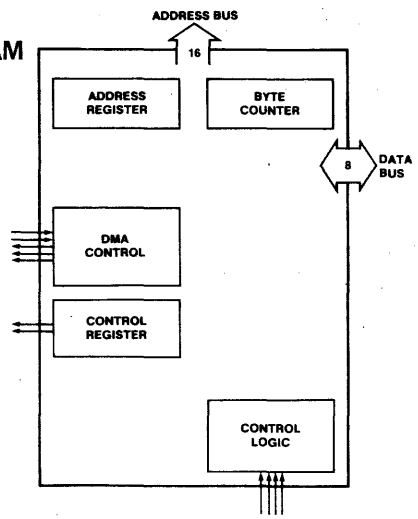
The 3853 Static Memory Interface (SMI) provides a programmable timer and external interrupt capability with a software loadable interrupt vector address in addition to the 16 address lines and memory control logic.



3853
SMI BLOCK DIAGRAM

©IC MASTER 1979

The 3857/38T57 Program Storage and Memory Interface (PSMI) provides 2K of ROM, an external interrupt and timer with masked interrupt vector as well as 16 address lines and memory control logic.

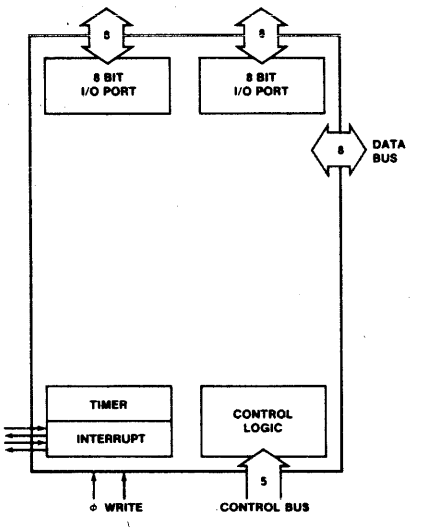


3857/38T57
PSMI BLOCK DIAGRAM

3854 Direct Memory Access (DMA)

The DMA circuits provide a high-speed data path between a system memory and the peripheral electronics with up to 500 kilo bytes of transparent data transfer per second. These circuits can transfer data blocks of up to 4096 bytes and can interrupt the CPU when this data transfer is complete or can be programmed to continue transferring until stopped.

3854
DMA BLOCK DIAGRAM

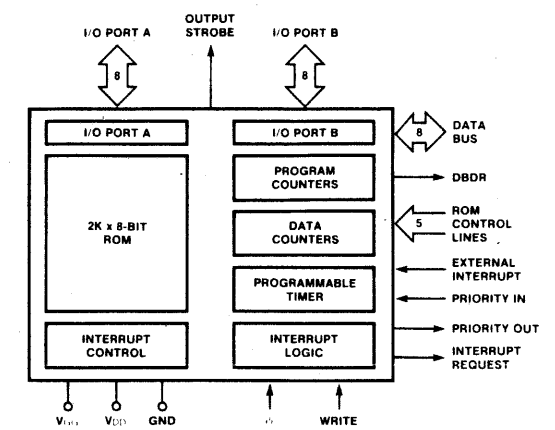


©IC MASTER 1979

3861/3871 Peripheral Input/Output

The 3861 PIO circuit contains all of the logic of the 3851 PSU without the 1K ROM. The 3861 is available in five versions as listed below.

TYPE	I/O PORTS	INTERRUPT ADDRESS VECTOR	
		TIMER	EXTERNAL
A	4-7	0600	0680
B	8-13	0340	03C0
C	20-23	0320	03A0
D	24-27	0360	03E0
E	4-7	0020	00A0



3861
PIO BLOCK DIAGRAM

The 3871 contains an improved timer and event counter. The 3871 is available in four versions as listed below.

TYPE	I/O PORTS	PORT TYPE	INTERRUPT ADDRESS VECTOR	
			TIMER	EXTERNAL
E	4-7	Standard	0020	00A0
F	4-7	Direct Drive	0020	00A0
G	4-7	Open Drain	0020	00A0
H	8-B	Standard	0420	04A0

THE FORMULATOR LINE OF F8 AND F3870 DESIGN AIDS

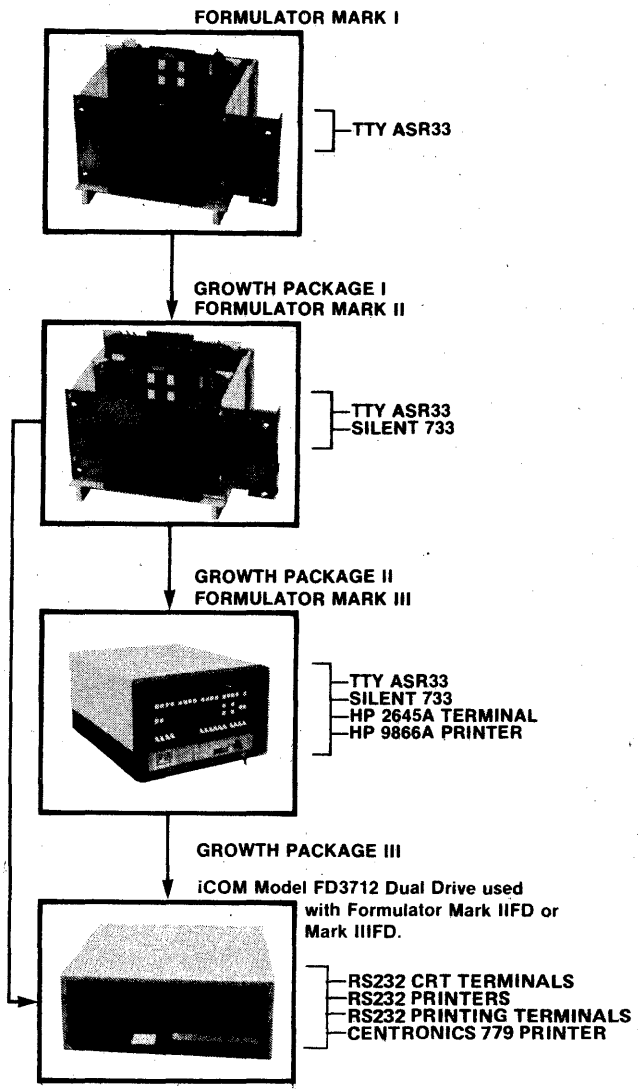
INTRODUCTION

The Microprocessor system designer can now create his own hardware and software development systems for the F8 and F3870 by selecting modular subassemblies from Fairchild's Formulator line of F8 and F3870 design aids. He may start development with a Mark I singleboard system, then expand to more sophisticated Mark II or Mark IIFD development systems that can handle both software and hardware development. Or he may graduate to a complete Formulator Mark III with intelligent front panel, power supply, and accessories or to the top of the line Formulator Mark IIIFD with floppy disk drives.

Three growth packages plus a selection of optional modules provide a practical method for upgrading the single-board Mark I to either the Mark II or Mark IIFD or to the maximum system configuration Mark III or Mark IIIFD. Using the growth packages, the designer can begin sophisticated system application programs at very low cost and then upgrade his development tools in relatively inexpensive steps, if he desires to do so at a later time.

The most elementary configuration, called the Formulator Mark I, includes a Processor module that contains an F8 CPU, Program Storage Unit that includes Fairbug monitor, Dynamic and Static Memory Interface circuits, 1024 bytes of random access memory, and the necessary buffers and other components for hardware development. It also includes a 13-slot card cage, an I/O cable kit, and a power cable.

The second level, the Formulator Mark II, includes all of the Mark I components plus a memory board with 16 kilobytes of RAM and the complete Formulator Operating System, designated FOS. FOS gives the user complete software development capability, including an assembler, editor, and debug package, and drivers for a teletype or the TI Silent 733 terminal.



The third level, the Formulator Mark IIFD, consists of the Mark II with the addition of interface cards and cables for an iCOM FD3712 dual-drive floppy disk system and Fairchild F8-DOS-III Floppy Disk Operating System.

The fourth level, the Formulator Mark III, includes an intelligent front panel, a serial communications module, a quad I/O module, an attractive cabinet, and a power supply. Also included are 16 kilobytes of RAM, the Formulator Processor Module, and the Formulator Operating System.

The top of the line is the Formulator Mark IIIFD. This microcomputer is identical to the Mark III with the addition of the iCOM dual drive floppy disk and interface.

Three growth packages are available for Mark I, Mark II, and Mark III expansion. Growth Package I upgrades the Mark I system to the Mark II level. Growth Package II converts the Mark II to the full Mark III level. Growth Package III upgrades either the Mark II or Mark III to the Mark IIFD or the Mark IIIFD floppy disk configurations.

Other boards are available as options for all five Formulator configurations to increase the flexibility of the units by adding to their capabilities. These include 4-kilobyte RAM, 4-kilobyte PROM, and 16-kilobyte RAM boards, as well as and I/O light board, a communications board with UART, a parallel-byte board for peripheral interface, and a PROM programmer.

FORMULATOR GROWTH PATHS

©IC MASTER 1979

FORMULATOR SUPPORT

In addition to the optional boards, peripherals, cables, and other accessories, the Mark I, Mark II, and Mark III Formulator systems are supported by a wide range of documentation, and an intensive training program.

FORMULATOR DOCUMENTATION

The Formulator user has access to a full range of reference and instructional manuals to aid him in his system design and programming.

F8 USER'S GUIDE

The F8 User's Guide is a detailed description of the F8 family of microprocessor devices. Microprocessor systems are discussed, with the configurations of the F8 circuits examined in depth. The User's Guide also outlines the F8 instruction set. Detailed specifications of each member of the F8 microprocessor family is given, including functional descriptions, logic diagrams, signal load levels, and timing diagrams for each circuit. Typical F8 system configurations are also presented.

GUIDE TO PROGRAMMING

The Guide to Programming is written for logic designers with little or no background in computer programming. It introduces machine and assembly language programming to the potential user of microprocessors and microcomputer systems. Introductory topics include flowcharting, memory allocation, source and object programs, and assembly language. More advanced topics include programmed /O, interrupts, programmable timers, subroutines, macros, data manipulation, and programmed direct memory access channels. Numerous examples of these programming techniques are given.

FORMULATOR USER'S GUIDE

The Formulator User's Guide fully describes the operation of the Formulator Development System. It covers the Mark I, Mark II, and Mark III hardware configurations and contains a detailed description of the Formulator software—the monitor, the editor, the assembler, and the debug program. The F8 DOS-III User's Guide is also available for Mark IIFD and Mark IIIFD systems.

FORMULATOR HARDWARE REFERENCE MANUAL

This book presents an in-depth technical description of the F8 Formulator System, its component subsystems, and options. The technical description includes general functional characteristics, theory of operation, and detailed description of interface signals.

F8 TRAINING CLASS

To help applications engineers start designing with the F8 microprocessor, Fairchild offers an intensive four-day training course. Lectures are presented dealing with F8 features, architecture, and programming. In laboratory sessions, students prepare and run small F8 programs using the Formulator development systems.

SOFTWARE SUPPORT

FOS— FORMULATOR OPERATING SYSTEM

The software for the Formulator products is specifically designed to assist engineers and programmers during the development phase of a microcomputer-based system. Designated the Formulator Operating System (FOS), this software package consists of a monitor, an editor, an assembler, a linking loader, a debug package, and several utility programs.

The editor assists the user in the creation of a source file, which the assembler then converts into an object file ready for loading into the system. This object file may, at the option of the user, be a relocatable file. If several such relocatable object files exist, they may be combined by the linking loader and assigned absolute addresses at loading.

The debug portion of FOS allows users to test for fast and efficient program testing, for setting software breakpoints, and for examining and altering memory, registers, and I/O ports.

Unlike other development systems with limited storage capability, the Formulator has enough memory so that the editor, relocating assembler, and debug packages are simultaneously resident, with transfer from one to the other controlled by the monitor. Thus, a program may be created, edited, assembled, and debugged without ever having to reload the system software, since the user may switch from the editor to the assembler to the debug program directly from the monitor.

The Formulator software also includes utility programs which perform specific functions. One, for instance, generates a file for producing a ROM code. Another creates a file needed by a PROM programmer. These utility programs are loaded into the system under the control of the monitor.

The combined effect of the interrelated portions of the Formulator Operating System is the rapid generation and checkout of F8 and F3870 microcomputer-based systems. These programs greatly simplify the effort required to develop and alter the end user software, making it easy to design and debug a system breadboard, easy in terms of reduced time and manpower.

FDOS–FORMULATOR DISK OPERATING SYSTEM

The software for the Formulator products is specifically designed to assist engineers and programmers during the development phase of a microcomputer-based system. Designated the F8 DOS-III, this software package consists of a floppy-disk monitor, an editor, a relocating assembler, a linking loader, a debug package, and utility programs.

The disk monitor provides all of the necessary commands for fast and efficient file management during the creation, editing, assembly, and debugging of applications programs.

The editor assists the user in the creation of a source file, which the assembler then converts into an object file ready for loading into the system. This object file may, at the option of the user, be a relocatable file. If several such relocatable object files exist, they may be combined by the linking loader and assigned absolute addresses at loading.

The debug portion of F8-DOS-III provides for fast and efficient testing. Under Software Control, the user can set software and hardware breakpoints, and examine and alter memory, registers, and I/O ports.

Unlike development systems with limited storage capability, the Formulator Mark IIFD has enough memory so that the editor, assembler, and debug packages are resident as needed with transfer from one to the other controlled by the disk monitor. Thus, a program may be created, edited, assembled, and debugged without ever having to externally reload the system software, since the user may switch from the editor to the assembler to the debug program directly from the disk monitor.

The Formulator software also includes utility programs which perform specific functions. One, for instance, generates a file for producing a ROM code; another creates a file needed by a PROM programmer. These utility programs are loaded into the system under the control of the disk monitor.

The combined effect of the interrelated portions of the F8 DOS-III is the rapid generation and checkout of F8 and F3870 microcomputer-based systems. These programs greatly simplify the effort required to develop and alter the end-user software, making it easy to design and debug a system breadboard, easy in terms of reduced time and manpower.

ICOM® Advertised FD3700 Series Features	F8-DOS-III SUMMARY			
	Disk Monitor	**Editor**	**Relocating Assembler**	**Real-Time Debugger**
Fully IBM 3740 media and format compatible	Assemble (Relocating)	Move Line	No-List Option	Symbolic Debugging
Full formatter and controller built-in	Load (Linking)	Copy Line	No-Object Option	Set Up to 8 Breakpoint

FORMULATOR MARK I

The first member of the Formulator family, the Formulator Mark I, is a basic microcomputer development tool providing the hardware necessary to build F8 or F3870 prototype systems. Included in the basic system is the Formulator Processor Module with the F8 CPU, Static Memory Interface, Dynamic Memory Interface, and Program Storage Unit devices. The Fairbug debug program, a 1K-byte monitor debug package, is included in the Program Storage Unit on the Processor Module. Fairbug provides the Mark I with sufficient debug capability to load a program, examine registers, monitor and alter memory locations, store a program on an external file, and generate a tape suitable for burning PROM memory devices. The Mark I also comes equipped with a 13-slot card cage and motherboard for attaching the modular Formulator printed circuit boards. Three slots are wired for the console control modules and one is dedicated to the Processor Module. The other nine connectors are general purpose slots which can accept additional Formulator modules for system expansion. Cables and documentation are also included in the F8 Formulator Mark I system, including a peripheral interface cable which can connect the Mark I to a Teletype ASR33 or TI Silent 733 for external communication.

THE FORMULATOR PROCESSOR MODULE

The Formulator Processor Module is the heart of the Formulator family of development systems. As illustrated in the block diagram below, the 10½" × 7½" Processor Module contains a Central Processor Unit (F3850 CPU), a Program Storage Unit (F3851A PSU) with the Fairbug monitor, a Static Memory Interface circuit (F3853 SMI), a Dynamic Memory Interface circuit (F3852 DMI), a 1K-byte RAM memory, and a peripheral interface circuit. Also included is the circuitry necessary to drive the Formulator bus for easy expansion of system functions. The 32 bidirectional I/O lines are brought out to the top edge connector; bus signals are brought to a connector on the bottom of the board. The board connector plugs into the Formulator motherboard where the signals are bussed to twelve other sockets. The peripheral interface signals are brought out to a special connector mounted on the Processor Module. They include both a 20 mA current loop and an RS232 interface circuit.

Two interrupt levels are available on the Formulator Processor Module, one from the F3851A PSU and the other from the F3853 SMI. The on-board F3852 DMI allows dynamic memory refresh and direct memory access functions to be incorporated into expanded memory systems.

Switches on the Processor Module change the page address of the 1K-byte RAM memory. Additional switches are provided to change the port addresses of the PSU circuit, enable and disable the Fairbug program, select the clock mode (LC, crystal, or external), enable the interrupt priority, and select serial interface devices (RS232 or current loop).

The Fairbug program, located in the F3851A PSU communicates with an ASCII serial device, reads data from a parallel paper tape reader, and punches tape. The Fairbug program also performs a debug function allowing users to examine and alter internal registers and memory.

PROCESSOR MODULE

FORMULATOR MARK II

The second member is the Formulator Mark II. This unit is a low cost microcomputer software and hardware development tool. It includes the basic hardware required to develop a system, as well as the necessary software tools to develop F8 and F3870 code. The Mark II consists of all the components of the Mark I, namely the Processor Module, card cage and motherboard, cable kit, and the Fairbug debug program, as well as an additional 16K-byte RAM module. Also a part of the Mark II is the Formulator Operating System, including the editor, relocating assembler, and debug package to allow the generation of the source codes and to create and check out the object codes. Peripheral interfaces are also available to connect the Mark II to a TI Silent 733 or Teletype ASR33.

FORMULATOR MARK IIFD

The third member is the Formulator Mark IIFD, a floppy-disk based low-cost microcomputer software and hardware development tool. It includes the basic hardware required to develop a system, as well as the necessary software tools to develop F8 and F3870 code. The Mark IIFD consists of all the components of the Mark I, namely the Processor Module, card cage and motherboard, cable kit, and the Fairbug debug program, as well as an additional 16K-byte RAM Module. The F8-DOS-III is also a part of the Mark IIFD. It includes a floppy-disk file manager, editor, relocating assembler, and debug package to generate the source codes and to create and check out the object codes. The Mark IIFD can communicate with teletype ASR33 and other standard RS232 CRT or printing terminals.

FORMULATOR MARK III

The fourth level of microprocessor development equipment is the Formulator Mark III, offering all of the design assistance required to develop F8 or F3970 based systems. The combination of hardware, software, and firmware offered by the Mark III assists the designer from the generation of source programs through the development of a prototype system. The Mark III is a modular microcomputer that accommodates a variety of memory, input/output, and communication configurations to form a new and powerful development system. It contains all of the components of the Mark II—the Processor Module, card cage and motherboard, cable kit, the Fairbug debug program, 16K bytes of RAM, and the Formulator Operating System. In addition, the Mark III includes a Quad I/O Module with four I/O ports and two interrupts, a Communications Module with an on-board UART, a universal breadboard for building user hardware configurations, an extender module, and an intelligent operator's panel. Power supplies for the Mark iii may be either 100 volts, 115 volts, or 220 volts at 50/60 Hz. Peripheral interfaces are available to connect the Mark III with a TI Silent 733, a Teletype ASR33, or an HP 2645A Mini-Data Station.

INTELLIGENT OPERATOR'S PANEL

Perhaps the most unique feature of the Mark III Formulator is the intelligent operator's panel, an array of lights and switches designed to give the user access to all registers and memory locations within the microcomputer, thus enabling an important interaction between the user and the system hardware and software.

The benefits of having a firmware controlled front panel are extensive. In addition to performing the normal front panel operations, such as examining and loading the contents of memory, the user's console can also perform some very complicated functions. Chief among these are the front panel's initial program load capability, its test function, and the real time hardware breakpoint feature.

The self test function is initiated by the user by merely depressing a single switch on the front panel. The console then begins to check the electronics in the Formulator. When an error condition is detected, the LED indicators on the display indicate the type of error and its location.

Another feature of the front panel is its ability, under operator control, to set a hardware breakpoint and to vary the number of times a memory location may be accessed before the break-in program execution occurs. This aids the user in performing fast, efficient debugging of his software.

MARK III FORMULATOR OPERATING SYSTEM

Like the Mark II Formulator Operating System, the Mark III FOS consists of a monitor, an editor, an assembler, a linking loader, a debug package, and several utility programs. In addition to the functions performed by each of these portions of the FOS in a Mark II system, the Mark III FOS includes the capability to set hardware breakpoints. It also contains a trace feature in the debug package which lets the user turn tracepoints on and off during the debug operation.

Two identical versions of the Formulator Operating System are available with the Formulator Mark III. One operates in the lower portion of memory and another operates in upper memory. The Low Memory Operating System resides in memory locations 1000 to 3FFF (Hex). Most of the lower 4K bytes of memory is reserved for user programs. The High Memory Operating System occupies locations with the hexadecimal addresses D000 to FFFF and uses the portion of memory from C000 to D000 to store the symbol table. With this system, the user has up to 48K bytes of continuous memory addresses available, eliminating the need for splitting programs larger than 4K bytes.

©IC MASTER 1979

FORMULATOR MARK IIIFD

The top of the line in microprocessor development equipment is the floppy-disk-based Formulator Mark IIIFD, offering all of the design assistance required to develop F8 or F3870 based systems. The combination of hardware, software, and firmware offered by the Mark IIIFD assists the designer from the generation of source programs through the development of a prototype system. The Mark IIIFD is a modular microcomputer that accommodates a variety of memory, input/output, and communication configurations to form a new and powerful development system. It contains all of the components of the Mark IIFD, the Processor Module, card cage and motherboard, cable kit, the Fairbug debug program, parallel interface, PROM boot loader, 16K bytes of RAM, and the F8-DOS-III disk operating system. In addition, the Mark IIIFD includes a quad I/O module with four I/O ports and two interrupts, a communications module with an on-board UART, a universal breadboard for building user hardware configurations, an extender module, and an intelligent operator's panel. Power supplies for the Mark IIIFD may be either 100 volts, 115 volts or 220 volts at 50/60 Hz. The Mark IIIFD can communicate with teletype ASR33 or other standard RS232 glass or printing terminals.

OPTIONAL FORMULATOR MODULES

Expansion of the Formulator microcomputers need not occur along the path indicated by the growth packages. Optional Formulator modules are available to expand RAM, PROM I/O, and communications, so the user can develop a custom system which is perfectly suited to his specific needs. These optional modules may be attached to the Formulator via the 13 card slots in the motherboard. The first three slots are dedicated to front panel operations of the Mark III. Another slot is reserved for the Processor Module. The remaining nine slots are linked on a common bus whose signals are compatible with the modules themselves. Additional system functions may be easily added to any Formulator system by simply plugging in one of the modules. Thus, the initial Formulator investment is preserved. Nothing needs to be discarded as demands upon the system increase. Unless otherwise noted, all of the following optional modules are available to update any Mark I, Mark II, Mark IIFD, Mark III, or Mark IIIFD system to meet expanded requirements.

Optional Modules

- 4K-Byte RAM Module
- 16K-Byte RAM Module
- Quad I/O Port Module
- 4K-Byte PROM Module
- Communications Module
- Byte Parallel Interface Module
- ROM Simulation Module
- Universal Breadboard
- Extender Module
- I/O Light Display Board

4K-BYTE RAM MODULE

The 4K-Byte Ram Module simplifies memory expansion in the Formulator Development Systems. Fully compatible with all Formulator bus signals, this board adds 4096 bytes of random access memory (using 2102 type static RAMs) to a system. Switches mounted on the printed circuit board allow the user to select the upper four address bits, so multiple memory modules may be used in a system. A write-protect switch puts the memory in a read-only mode at the user's discretion. Board dimensions are 10½" × 7½".

EXTENDER MODULE

During the checkout of the user's own breadboard systems, the Formulator Extender Module can be used to facilitate access to the user's hardware configuration contained on the universal breadboard. The 10½" × 7½" extender module plugs directly into the Formulator motherboard, and the module to be examined attaches to the 100-pin connector on the top edge of the extender card. Thus, the user's module is elevated above the other modules in the Formulator card cage for easy access.

©IC MASTER 1979

16K-BYTE RAM MODULE

The 16K-Byte RAM Module provides additional modularly expandable memory for the Formulator Development System. Fully compatible with all Formulator bus signals, this board adds 16 kilobytes of random access memory (4K N-MOS Dynamic RAM) to a system. Switches mounted on the printed circuit board allow the user to select the upper two address bits, so multiple memory modules may be used in a system. Four write-protect switches put the memory in a 'read only' mode at the user's discretion. The refresh of the dynamic memory is controlled by the F3852 Dynamic Memory Interface circuit mounted on the Processor Module. The refresh cycles are performed during unused data bus periods, and do not interfere with normal system timing. The board dimensions are 10½" × 7½".

4K-BYTE PROM MODULE

Additional memory expansion in the Formulator systems may be easily performed with the use of the 4K-Byte PROM Module. This board adds 4096 bytes of nonvolatile memory storage capability. It provides 16 sockets for the Fairchild 93446 TTL fuseable link 512 × 4-bit PROMs configured in a 4-kilobyte array. Four switches mounted on the printed circuit board allow the memory page to be switch selectable. All data bus and control bus signals are compatible with the Formulator system, so the board plus directly into the Formulator motherboard. The 93446 PROM devices may be programmed by the Formulator PROM Programmer. The board dimensions are 10½" × 7½".

ROM Simulation Module

The ROM Simulation Module allows the user to interface the F3851A and F3856 Program Storage Units to the Formulator systems. Two of these 40-pin devices may be inserted in each ROM Simulation Module, creating an excellent environment for checking out ROM codes stored on the PSUs.

BYTE PARALLEL INTERFACE MODULE

The Byte Parallel Interface Module interfaces the Formulator system to external devices in a parallel format. This 10½" × 7½" module creates a data bus and a control bus for passing information to and from the system. The bidirectional data bus can be used for either 8- or 16-bit parallel words. The 8-bit control bus synchronizes data transfer to and from the Formulator system. The F8 I/O ports. One level of F8 interrupt logic and one F8 interval timer are also available to the user. On-board switches select the F8 interrupt address vector and the F8 I/O port addresses. The signal levels for the device interface are given below.

Receive

V_{IL}	I_{IL}	V_{IH}	I_{IH}	V_{CC}
0.4V	−0.2mA	5.25V	25 μA	5.25V

Drive

V_{OL}	I_{OL}	V_{OH}	I_{OH}	V_{CC}
0.5V	48mA	2.4V	−10mA	4.75V

QUAD I/O PORT MODULE

The Quad I/O Port Module makes expanding the Formulator I/O capability an easy task. This board uses existing F8 I/O ports, so actual F8 signal levels are brought out to the edge connector on the top of the module. This module has two F8 circuits, each with two I/O ports, one interrupt level, and one programmable timer. Thus, a total of four ports (32 bits), two interrupt levels, and two timers are available to the user. Switches mounted on the card allow the user to select the I/O port addresses and the interrupt vector addresses for each F8 circuit. Thus, since each board may use different I/O ports, multiple boards may be used in a system. The board dimensions are 10½" × 7½".

COMMUNICATIONS MODULE

The Communications Module provides the electrical interface for any one of three types of serial peripheral devices, a standard teletype 20 mA current loop, RS-232 interface, or a TTL compatible device. An on board UART (Universal Asynchronous Receiver Transmitter) is used to perform the conversion between the 8-bit parallel microcomputer data and the serial signal, thus permitting high speed data transfer. Thirteen baud rates, ranging from 50 to 9600 baud, can be set from switches mounted on the card. A crystal is used to ensure accurate timing. The UART-microcomputer interface is maintained via two F8 I/O ports, also located on the printed circuit board. The F8 timer and interrupt logic are also available to the user, with the interrupt address vector and F8 I/O port numbers switch selectable. Board dimensions are 10½" × 7½".

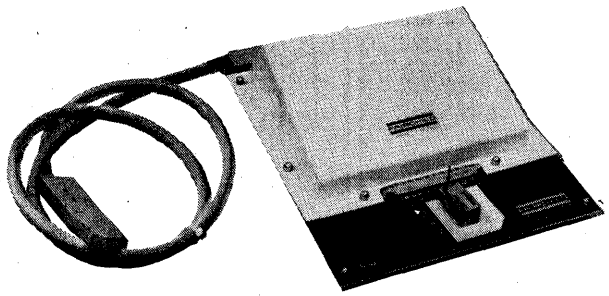
I/O LIGHT DISPLAY BOARD

The I/O Light Display Board monitors the status of the F8 I/O signals of either the Formulator Processor Module or the Formulator Quad I/O Module. Mounted on the printed circuit cards are red LEDs, grouped in two rows of twenty, allowing up to four I/O ports plus power supplies to be viewed simultaneously. On-board drivers provide sufficient current levels to drive the LEDs. Additional lights on the board show the status of the external interrupts. The board dimensions are 10½" × 4½".

UNIVERSAL BREADBOARD

The universal breadboard is an empty Formulator module board which can aid in the development of the user's own breadboards. It is a 10½" × 7½" Formulator motherboard-compatible module which is predrilled to accept standard 14, 16, 18, 22, 24, and 40-pin dual inline packages. It will accomodate forty-four 16-pin packages. With the universal breadboard, the Formulator user may design his own breadboard configuration of non-microprocessor circuits while in constant contact with the microprocessor development tools of the Formulator.

©IC MASTER 1979



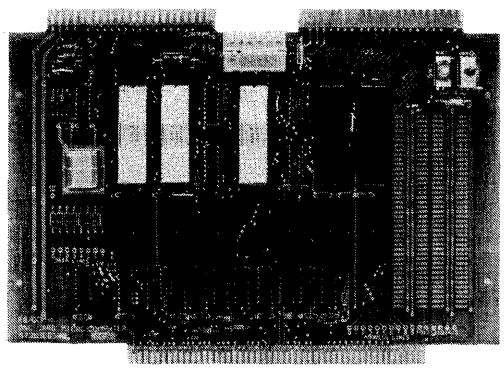
PROM PROGRAMMER

The ability to easily program permanent memory devices is essential to any microprocessor design. The Formulator PROM Programmer connects to a Quad I/O Module within either a Formulator Mark II or a Formulator Mark III, permitting the programming of any of the following fuseable link or ultraviolet light eraseable PROMs from a pattern stored in the Formulator memory.

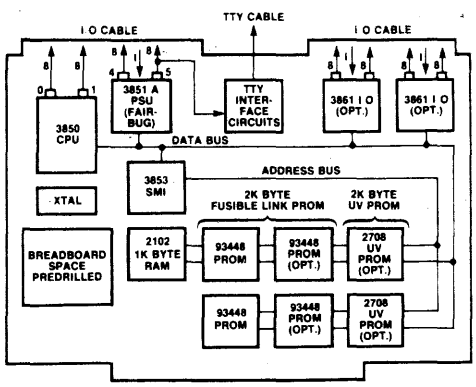
The 11" × 12" × 4" PROM Programmer is driven by a utility program contained within the Formulator Operating System and features a simple, easy to use command set. The commands, entered into the PROM Programmer from the Formulator peripheral via the keyboard, allow the user to transfer data from a PROM to memory, burn a PROM, verify a PROM pattern, manually enter a single byte of data, and display PROM locations using the system software. The programming idiosyncrasies of each PROM are contained in software look-up tables to relieve the user of intricate repetitious set-up. The procedure is simply to identify the PROM type (like 93448) and the PROM parameter look-up table is automatically invoked, defining such things as number of words, word bit length, burn time, wait time, retry conditions, etc. The programming is convenient enough to allow the PROM Programmer to be used in a production environment.

Included in the basic system are two socket boards, one for the Fairchild 93436/93446 PROMs and one for the 93438/93448 PROMs. Socket boards for the ultraviolet eraseable devices are also available. A cable to the Quad I/O Module and a power cord are also included in the basic unit.

Fairchild Fusible Link PROMS	Ultraviolet Eraseable PROMs
93436 (512 × 4)	2704 (512 × 8)
93446 (512 × 4)	2708 (1024 × 8)
93438 (512 × 8)	2716
93448 (512 × 8)	



OCM-1 ONE-CARD MICROCOMPUTER



The OCM-1 is a complete microcomputer system contained on a single printed circuit board and offering the following features:

- 64-byte scratch pad memory
- 1K-byte RAM
- 8K-byte ROM (1K supplied, sockets provided for balance)
- 4K-byte EPROM (sockets provided)
- 4K-byte PROM (sockets provided)
- Up to four programmable timers
- Up to four programmable interrupts
- RS232 interface (current loop optional)
- 2 MHz clock
- Self-contained Fairbug teletype operating system
- Up to 64 individually programmable, bidirectional, latched I/O lines.

The unit is based on the F8 microcomputer and is fully supported by the Formulator family of program development aids. In addition, the OCM-1 contains a built-in teletype operating system, called Fairbug I, contained in the F3851A Program Storage Unit. Using an OCM-1-to-TTY cable assembly, the board can be directly coupled to a teletype or RS232 terminal to display or alter memory location, to load and punch paper tape, or to make entries from the keyboard or by program instruction. An alternative built-in operating system, K-D Bug, contained in the F3856A PSU is also available. It provides all of the Fairbug I functions plus a resident monitor to facilitate operation with a low-cost calculator-style keyboard and LED display. A Fairbug user's guide is provided with the OCM-1. The K-D Bug should be ordered as a separate item.

OCM-1 Module

OCM-1 Block Diagram

©IC MASTER 1979

The OCM-1 processor section includes the 3850 Central Processing Unit, the F3853 Static Memory Interface, a 2 MHz clock, and reset circuitry.

The OCM-1 memory section contains the capability for the use of five different types of storage including 64 bytes of scratch pad, 1K bytes of RAM, sockets for 2K bytes of EROM (2708), sockets for 2K bytes of fusible link PROM (93448), and the Fairbug I operating system.

The I/O portion of the system is contained in the F3850 Central Processing Unit and a F3851A Program Storage Unit, each containing two 8-bit I/O ports. Two sockets are provided for inserting standard F8 PIO circuits (F3861 or F3871) or, if more ROM is required, standard PSUs (F3851 or F3856) may be inserted. In either case, four additional I/O ports are provided bringing the maximum total to eight I/O ports (64 lines). Only single-byte instructions are required to individually program these lines for either input or output functions. Latches on each line reduce external hardware cost. A circuit on the board gives the OCM-1 the capability of communicating with a teletype, RS232 device or 20mA current loop.

In its standard configuration, the OCM-1 contains two interrupts and two timers, one in the F3851A PSU and one in the F3853 SMI. Two additional interrupts and timers may be added by plugging the two additional PIOs into their sockets. A "daisy-chained" priority system determines which interrupt will be serviced if two or more requests are made simultaneously.

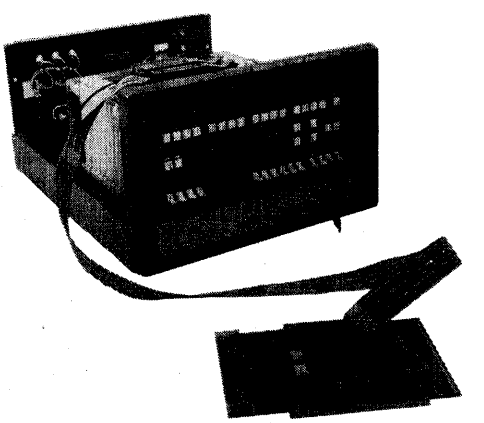
The OCM-1 requires three power supply voltages: +12 V @ 0.255 A, −5 V @ 0.4 A and −5 V @ 0.09 A. The −5V supply is used only for the 2708 EROM devices. All supply voltages are ± 5 % maximum.

The entire microcomputer is contained on a single board (epoxy glass with solder mask) measuring approximately 7.5 inches by 10.5 inches. It includes a 2-inch by 4-inch predrilled breadboarding area for users who want to develop unique system configurations. In addition, a Formulator-compatible 100-pin edge connector, a special connector for TTY or terminal, and two 44-pin edge connectors for F8 signals, are contained on the board. A switch to enable the Fairbug operating system is also provided. The OCM-1 is delivered completed with OCM-1 Users Manual, Fairbug Users Guide and F8 Guide to Programming.

F387X PEP SYSTEM—PROGRAMMING EMULATING PROTOTYPING SYSTEM

A standalone single board system with Keyboard Display, Firmware Monitor, PROM Programming facilities is described previously in this section.

F3870 DEVELOPMENT SUPPORT

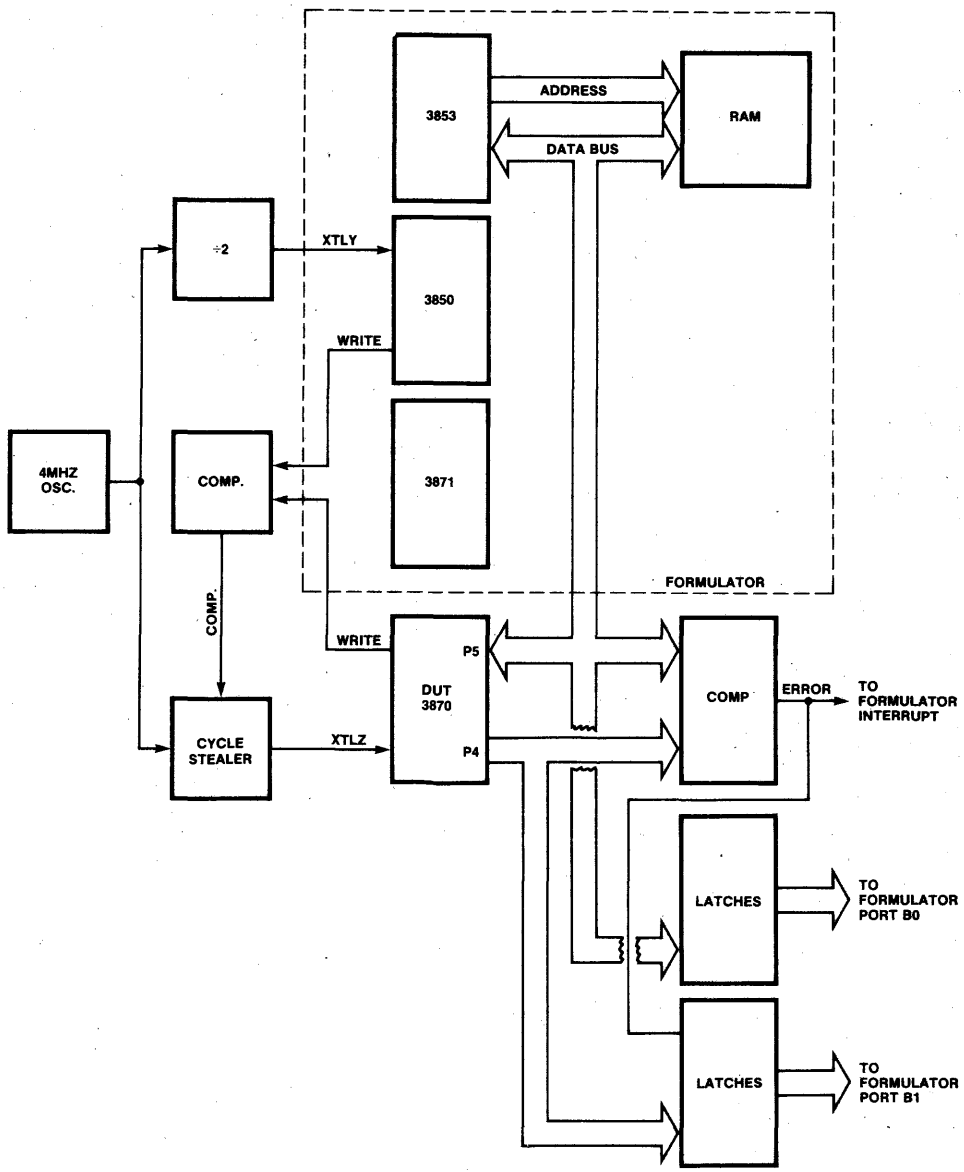


The F8 Formulator family of development equipment also supports the F3870, the one-chip microcomputer manufactured by Fairchild. The Formulator Operating System, utility program, and the Fairbug monitor are completely compatible with the F3870, since it shares the same instruction set with the Formulator. A Simulation (Quad I/O) Module and an In-Circuit Emulation (ICE) cable are available to extend the Formulator features to the user's prototype or production breadboard. This creates a powerful design tool for creating the user's own F3870 software. In addition, the F3870 Emulator, a single stand-alone module for emulating the final F3870 software in PROMs, is available for building prototype systems.

F3870 SIMULATION

The non-microprocessor elements of the user's hardware configuration can be assembled on a breadboard and connected to Mark I, II, IIFD, III or IIIFD via the ICE cable plugged into a 40-pin socket on the user's board. The cable connector on the Processor Module in the Formulator provides I/O ports 0 and 1, while the Simulation (Quad I/O) Module provides I/O ports 4 and 5. This system provides real-world simulation of the user's components in their actual environment with the vital microprocessor signals, including the complete software debugging features of the Formulator, cabled to the external breadboard.

F3870 EMULATOR



After F3870 ROM codes are frozen, a smaller, easier-to-handle and less expensive tool is required. To accomplish this design-in task, Fairchild has developed the F3870 Emulator. The F3870 Emulator contains sockets for two 2708s or two 2716 EROMs in place of the F3870 on-chip ROM so ROM codes can be verified and easily changed. The F3870 Emulator plugs directly into the F3870 40-pin socket in the production prototype using a short Emulator cable. The printed circuit module is approximately 5″ by 7 ″.

F387X Functional Tester

- Complete function testing for F387X
- Available as an accessory for the Formulator development system
- No "Gold device" needed
- Load ROM code to RAM then compare to F387X
- GO/NO GO or complete diagnostic printout available
- Low cost system
- Complete software test program provided for Formulator Mark II or Mark III

Formulator Tester for F3870

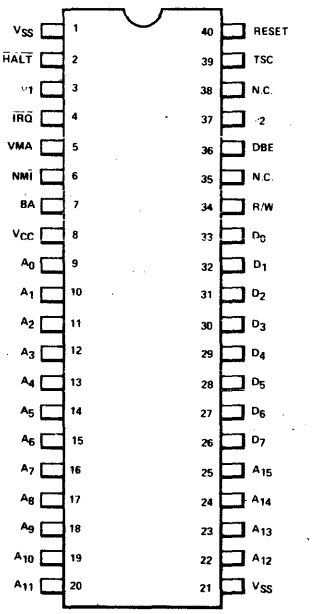
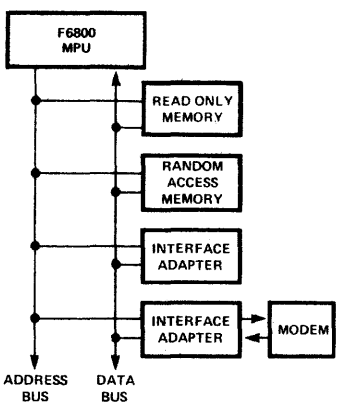
F6800

MICROPROCESSING UNIT (MPU)



FAIRCHILD F6800 MICROCOMPUTER FAMILY

GENERAL DESCRIPTION – The F6800 is a monolithic 8-bit microprocessor forming the central control function for Fairchild's F6800 family. Compatible with TTL, the F6800, as with all F6800 system parts, requires only one 5.0 V power supply and no external TTL devices for bus interface.



The F6800 is capable of addressing 65K bytes of memory with its 16-bit address lines. The 8-bit data bus is bi-directional as well as 3-state, making direct memory addressing and multiprocessing applications possible. Two temperature ranges are available. The F6800 is 0°C to 70°C and the F6800C is –40°C to +85°C.

- **8-BIT PARALLEL PROCESSING**
- **BI-DIRECTIONAL DATA BUS**
- **16-BIT ADDRESS BUS – 65K BYTES OF ADDRESSING**
- **72 INSTRUCTIONS – VARIABLE LENGTH**
- **SEVEN ADDRESSING MODES – DIRECT, RELATIVE, IMMEDIATE, INDEXED, EXTENDED, IMPLIED AND ACCUMULATOR**
- **VARIABLE LENGTH STACK**
- **VECTORED RESTART**
- **MASKABLE INTERRUPT VECTOR**
- **SEPARATE NON-MASKABLE INTERRUPT – INTERNAL REGISTERS SAVED IN STACK**
- **SIX INTERNAL REGISTERS – TWO ACCUMULATORS, INDEX REGISTER, PROGRAM COUNTER, STACK POINTER AND CONDITION CODE REGISTER**
- **DIRECT MEMORY ADDRESSING (DMA) AND MULTIPLE PROCESSOR CAPABILITY**
- **CLOCK RATES 1 MHz, 1.5 MHz, 2 MHz**
- **SIMPLE BUS INTERFACE WITHOUT TTL**
- **HALT AND SINGLE INSTRUCTION EXECUTION CAPABILITY**
- **TWO TEMPERATURE RANGES – F6800 0°C TO 70°C**
  F6800C –40°C TO +85°C

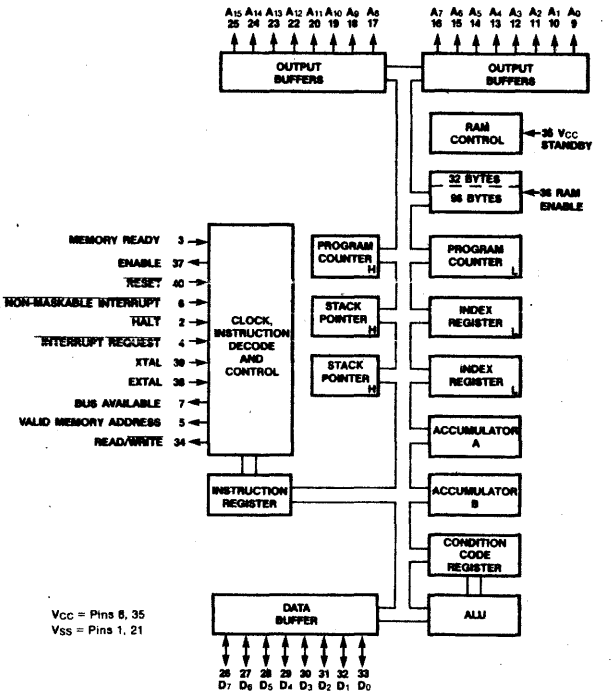
F6800 MICROPROCESSING UNIT (MPU)

GENERAL DESCRIPTION – The F6800 is a monolithic 8-bit microprocessor forming the central control function for Fairchild's F6800 family. Compatible with TTL, the F6800, as with all F6800 system parts, requires only one 5.0 V power supply and no external TTL devices for bus interface.

The F6800 is capable of addressing 65K bytes of memory with its 16-bit address lines. The 8-bit data bus is bi-directional as well as 3-state, making direct memory addressing and multiprocessing applications possible. Two temperature ranges are available. The F6800 is 0°C to 70°C and the F6800C is –40°C to +85°C.

- 8-BIT PARALLEL PROCESSING
- BI-DIRECTIONAL DATA BUS
- 16-BIT ADDRESS BUS – 65K BYTES OF ADDRESSING
- 72 INSTRUCTIONS – VARIABLE LENGTH
- SEVEN ADDRESSING MODES – DIRECT, RELATIVE, IMMEDIATE, INDEXED, EXTENDED, IMPLIED AND ACCUMULATOR
- VARIABLE LENGTH STACK
- VECTORED RESTART
- MASKABLE INTERRUPT VECTOR
- SEPARATE NON-MASKABLE INTERRUPT – INTERNAL REGISTERS SAVED IN STACK
- SIX INTERNAL REGISTERS – TWO ACCUMULATORS, INDEX REGISTER, PROGRAM COUNTER, STACK POINTER AND CONDITION CODE REGISTER
- DIRECT MEMORY ADDRESSING (DMA) AND MULTIPLE PROCESSOR CAPABILITY
- CLOCK RATES 1 MHz, 1.5 MHz, 2 MHz
- SIMPLE BUS INTERFACE WITHOUT TTL
- HALT AND SINGLE INSTRUCTION EXECUTION CAPABILITY
- TWO TEMPERATURE RANGES – F6800 0°C TO 70°C
  F6800C –40°C TO +85°C



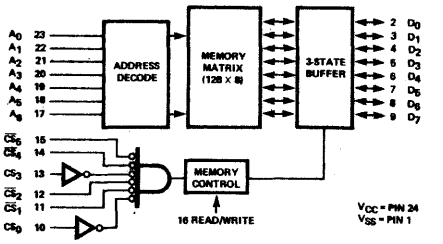
F6800 MPU

F6802 MICROPROCESSING UNIT (MPU) WITH RAM AND CLOCK

GENERAL DESCRIPTION—The F6802 is a monolithic 8-bit microprocessor that contains all the registers and accumulators of the present F6800 plus an internal clock oscillator and driver on the same chip. In addition, the F6802 has 128 bytes of RAM on board located at hex addresses 0000 to 007F. The first 32 bytes of RAM, at hex addresses 0000 to 001F, may be retained in a low power mode by utilizing V_{CC} standby, thus facilitating memory retention during a power-down situation.

The F6802 is completely software compatible with the F6800 as well as the entire F6800 family of parts. Hence, the F6802 is expandable to 64K words.

- ON-CHIP CLOCK CIRCUIT
- 128 x 8-BIT ON-CHIP RAM
- 32 BYTES OF RAM ARE RETAINABLE
- SOFTWARE-COMPATIBLE WITH THE F6800
- EXPANDABLE TO 64K WORDS
- STANDARD TTL-COMPATIBLE INPUTS AND OUTPUTS
- 8-BIT WORD SIZE
- 16-BIT MEMORY ADDRESSING
- INTERRUPT CAPABILITY
- TWO TEMPERATURES RANGES – F6802 0°C to 70°C
  F6802C –40°C to 85°C



F6802 MPU

F6810 RANDOM ACCESS MEMORY (RAM)

GENERAL DESCRIPTION – F6810 is a byte-organized memory designed for use in bus-organized systems. It is fabricated with N-channel silicon-gate technology. For ease of use, the device operates from a single power supply, has compatibility with TTL and DTL, and needs no clocks or refreshing because of static operation.

The memory is compatible with the F6800 Microcomputer Family, providing random storage in byte increments. Memory expansion is provided through multiple Chip Select inputs.

- ORGANIZED AS 128 BYTES OF EIGHT BITS
- STATIC OPERATION
- BI-DIRECTIONAL 3-STATE DATA INPUT/OUTPUT
- SIX CHIP SELECT INPUTS (FOUR ACTIVE LOW, TWO ACTIVE HIGH)
- SINGLE 5 V POWER SUPPLY
- TTL COMPATIBLE
- MAXIMUM ACCESS TIME = 350 ns – F6810-1
  450 ns – F6810

F6810 RAM

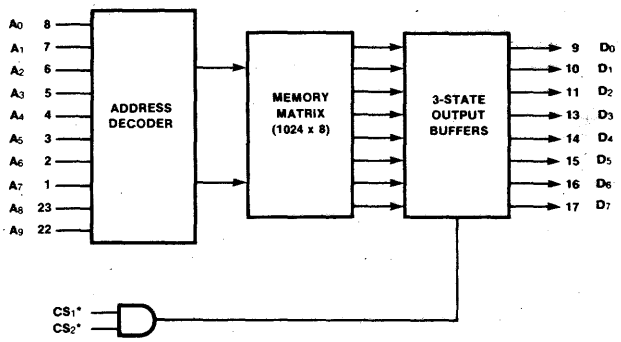
F6821 PERIPHERAL INTERFACE ADAPTOR (PIA)

GENERAL DESCRIPTION — The F6821 Peripheral Interface Adapter provides the universal means of interfacing peripheral equipment to the F6800 Microprocessing Unit (MPU). This device is capable of interfacing the MPU to peripherals through two 8-bit bi-directional peripheral data buses and four control lines. No external logic is required for interfacing to most peripheral devices.

The functional configuration of the PIA is programmed by the MPU during system initialization. Each of the peripheral data lines can be programmed to act as an input or output, and each of the four control/interrupt lines may be programmed for one of several control modes. This allows a high degree of flexibility in the overall operation of the interface.

- 8-BIT BI-DIRECTIONAL DATA BUS FOR COMMUNICATION WITH THE MPU
- TWO BI-DIRECTIONAL 8-BIT BUSES FOR INTERFACE TO PERIPHERALS
- TWO PROGRAMMABLE CONTROL REGISTERS
- TWO PROGRAMMABLE DATA DIRECTION REGISTERS
- FOUR INDIVIDUALLY-CONTROLLED INTERRUPT INPUT LINES; TWO USABLE AS PERIPHERAL CONTROL OUTPUTS
- HANDSHAKE CONTROL LOGIC FOR INPUT AND OUTPUT PERIPHERAL OPERATION
- HIGH IMPEDANCE 3-STATE AND DIRECT TRANSISTOR DRIVE PERIPHERAL LINES
- PROGRAM CONTROLLED INTERRUPT AND INTERRUPT DISABLE CAPABILITY
- CMOS DRIVE CAPABILITY ON SIDE A PERIPHERAL LINES



F6821 PIA

F68308 READ ONLY MEMORY (ROM)

GENERAL DESCRIPTION — The F68308 is a mask-programmable byte-organized memory designed for use in bus-organized systems. It is fabricated with n-channel silicon-gate technology. For ease of use, the device operates from a single power supply, has compatibility with TTL and DTL, and needs no clocks or refreshing because of static operation.

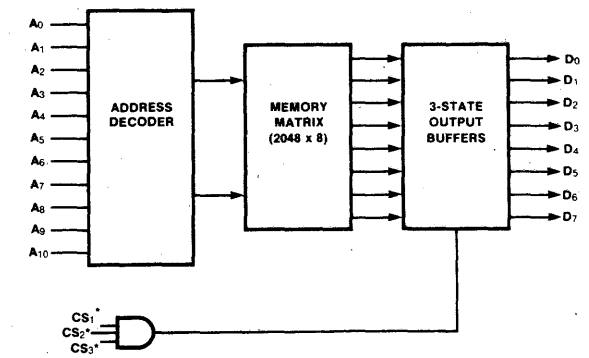
The memory is compatible with the F6800 Microcomputer Family, providing read only storage in byte increments. Memory expansion is provided through multiple Chip Select inputs. The active level of the Chip Select inputs and the memory content are defined by the customer.

- ORGANIZED AS 1024 BYTES OF 8 BITS
- STATIC OPERATION
- 3-STATE DATA OUTPUT
- MASK-PROGRAMMABLE CHIP SELECTS FOR SIMPLIFIED MEMORY EXPANSION
- SINGLE 5 V POWER SUPPLY
- TTL COMPATIBLE
- MAXIMUM ACCESS TIME = 500 ns
- 350 mW TYPICAL POWER DISSIPATION
- PIN COMPATIBLE WITH 2708 EPROM

*Active level defined by the customer.

VCC = Pin 24
GND = Pin 12

F68308 ROM



F68316 READ ONLY MEMORY (ROM)

GENERAL DESCRIPTION — The Fairchild F68316 is a mask-programmable byte-organized MOS Read Only Memory designed for use in bus-organized systems requiring non-volatile data storage. It is fabricated with n-channel silicon-gate technology. For ease of use, the F68316 operates from a single 5 V power supply, inputs and outputs are TTL and DTL compatible, and the device needs no clocks or refreshing because of its static operation.

The F68316 is compatible with Fairchild's F6800 Microcomputer Family providing read only storage in byte increments. To facilitate memory expansion, the device contains three programmable Chip Select inputs providing any combination of active HIGH or LOW or an optional DON'T CARE state coupled with output OR-TIE capability. Chip select code and memory content are defined by the user and are fixed during the masking process.

The F68316 provides maximum circuit density, reliability and performance yet maintains low power dissipation and yields significant cost advantages over an EPROM approach.

- COMPLETELY STATIC OPERATION
- 2048 x 8-BIT BUS COMPATIBLE ORGANIZATION
- SINGLE 5 VOLT POWER SUPPLY
- TTL AND DTL COMPATIBLE INPUTS
- 3-STATE DATA OUTPUTS
- OR-TIE CAPABILITY
- THREE PROGRAMMABLE CHIP SELECTS FOR SIMPLIFIED MEMORY EXPANSION
- MAXIMUM ACCESS TIME = 500 ns
- PIN COMPATIBLE WITH F2708 PROM
- DIRECTLY COMPATIBLE WITH 2316E

VCC = Pin 24
GND = Pin 12

*Active level defined by the user.

F68316 ROM

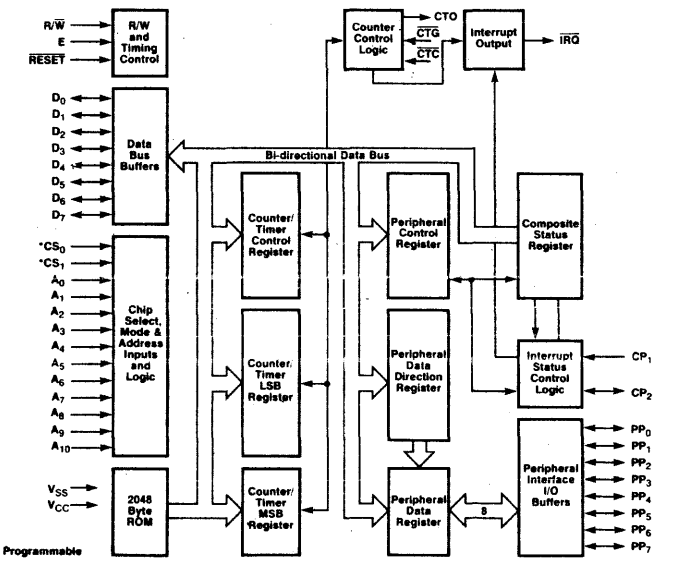
F6840 PROGRAMMABLE TIMER (PTM)

GENERAL DESCRIPTION—The F6840 is a programmable subsystem component of the F6800 family designed to provide variable system time intervals.

The F6840 has three 16-bit binary counters, three corresponding control registers and a status register. These counters are under software control and may be used to cause system interrupts and/or generate output signals. The F6840 may be utilized for such tasks as frequency measurements, event counting, interval measuring and similar tasks. The device may be used for square wave generation, gated delay signals, single pulses of controlled duration, and pulse width modulation as well as system interrupts.

- OPERATES FROM A SINGLE 5 VOLT POWER SUPPLY
- FULLY TTL COMPATIBLE
- SINGLE SYSTEM CLOCK REQUIRED (ENABLE)
- SELECTABLE PRESCALER ON TIMER 3 CAPABLE OF A 4 MHz INPUT
- PROGRAMMABLE INTERRUPTS ($\overline{IRQ}$) OUTPUTS TO MPU
- READABLE DOWN COUNTER INDICATES COUNTS TO GO TO TIME-OUT
- SELECTABLE GATING FOR FREQUENCY OR PULSE-WIDTH COMPARISON
- $\overline{RESET}$ INPUT
- THREE ASYNCHRONOUS EXTERNAL CLOCK AND GATE/TRIGGER INPUTS INTERNALLY SYNCHRONIZED
- THREE MASKABLE OUTPUTS



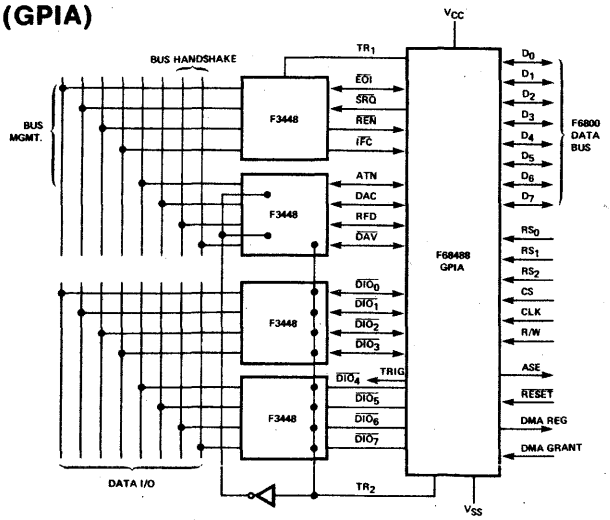
F6840 PTM

F6846 ROM-I/O-TIMER

GENERAL DESCRIPTION–The F6846 combination chip provides the means, in conjunction with the F6802, to develop a basic 2-chip microcomputer system. The F6846 consists of 2048 bytes of mask programmable ROM, an 8-bit bi-directional data port with control lines, and a 16-bit programmable timer-counter.

This device is capable of interfacing with the F6802 (basic F6800, clock and 128 bytes of RAM) as well as the F6800 if desired. No external logic is required to interface with most peripheral devices.

- 2048 8-BIT BYTES OF MASK-PROGRAMMABLE ROM
- 8-BIT BI-DIRECTIONAL DATA PORT FOR PARALLEL INTERFACE PLUS TWO CONTROL LINES
- PROGRAMMABLE INTERVAL TIMER-COUNTER FUNCTIONS
- PROGRAMMABLE I/O PERIPHERAL DATA, CONTROL AND DIRECTION REGISTERS
- COMPATIBLE WITH THE COMPLETE F6800 MICROCOMPUTER PRODUCT FAMILY
- TTL-COMPATIBLE DATA AND PERIPHERAL LINES
- SINGLE 5 VOLT POWER SUPPLY



F6846 RIOT

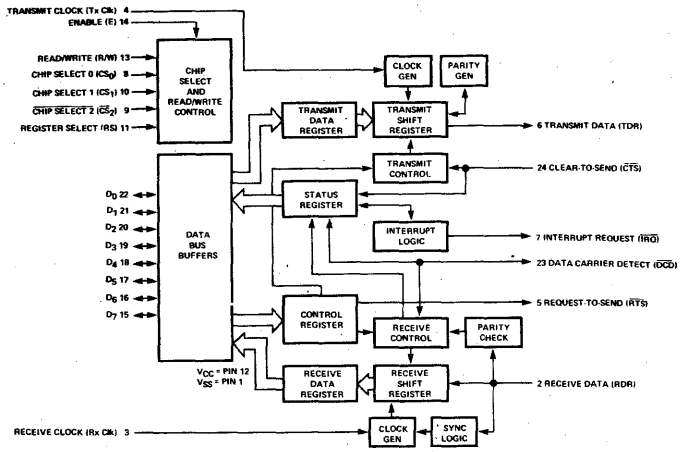
F68488 GENERAL PURPOSE INTERFACE ADAPTER (GPIA)

GENERAL DESCRIPTION—The F68488 GPIA provides the means to interface between the IEEE 488 standard instrument bus and the F6800. The 488 instrument bus provides a means for controlling and moving data from complex systems of multiple instruments.

The F68488 will automatically handle all handshake protocol needed on the instrument bus.

- SINGLE OR DUAL PRIMARY ADDRESS RECOGNITION
- SECONDARY ADDRESS CAPABILITY
- COMPLETE SOURCE AND ACCEPTOR HANDSHAKES
- PROGRAMMABLE INTERRUPTS
- RFD HOLD-OFF TO PREVENT DATA OVERRUN
- OPERATES WITH DMA CONTROLLER
- SERIAL AND PARALLEL POLLING CAPABILITY
- TALK-ONLY OR LISTEN-ONLY CAPABILITY
- SELECTABLE AUTOMATIC FEATURES TO MINIMIZE SOFTWARE
- SYNCHRONIZATION TRIGGER OUTPUT
- F6800 BUS COMPATIBLE

F68488 GPIA INTERFACE



©IC MASTER 1979

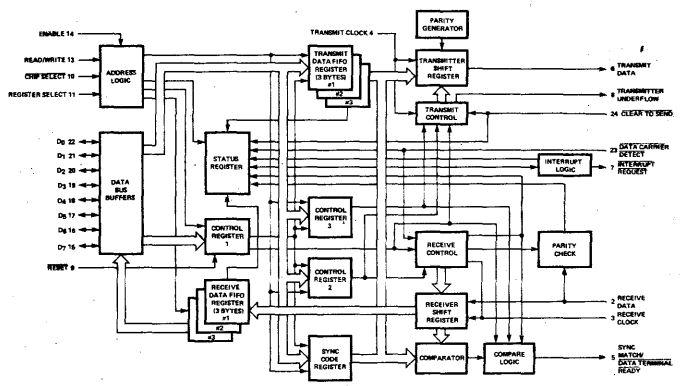
F6850 ASYNCHRONOUS COMMUNICATIONS INTERFACE ADAPTOR (ACIA)

GENERAL DESCRIPTION – The F6850 Asynchronous Communications Interface Adapter (ACIA) provides the data formatting and control to interface serial asynchronous data communications information to bus organized systems such as the F6800 Microprocessing Unit.

The bus interface of the F6850 includes select, enable, read/write, interrupt and bus interface logic to allow data transfer over an 8-bit bi-directional data bus. The parallel data of the bus system is serially transmitted and received by the asynchronous data interface, with proper formatting and error checking. The functional configuration of the ACIA is programmed via the data bus during system initialization. A programmable Control Register provides variable word lengths, clock division ratios, transmit control, receive control, and interrupt control. For peripheral or modem operation, three control lines are provided. These lines allow the ACIA to interface directly with the F6860 0-600 bps digital modem.

- 8 AND 9-BIT TRANSMISSION
- OPTIONAL EVEN AND ODD PARITY
- PARITY, OVERRUN AND FRAMING ERROR CHECKING
- PROGRAMMABLE CONTROL REGISTER
- OPTIONAL ÷1, ÷16, AND ÷64 CLOCK MODES
- UP TO 500 kbps TRANSMISSION
- FALSE-START BIT DELETION
- PERIPHERAL/MODEM CONTROL FUNCTIONS
- DOUBLE BUFFERED
- ONE OR TWO STOP BIT OPERATION

F6850 ACIA



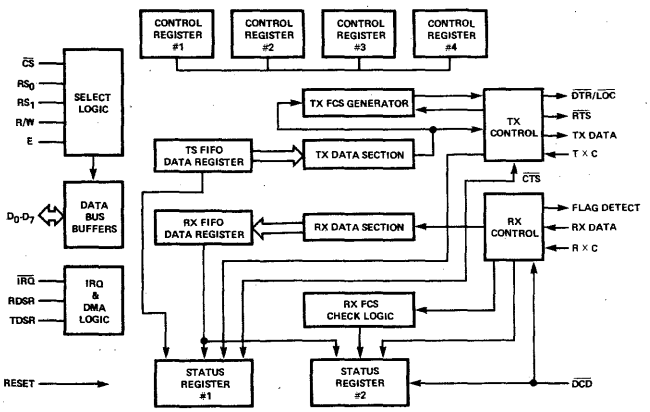
F6852 SYNCHRONOUS SERIAL DATA ADAPTOR (SSDA)

GENERAL DESCRIPTION – The F6852 Synchronous Serial Data Adapter provides a bi-directional serial interface for synchronous data information interchange. It contains interface logic for simultaneously transmitting and receiving standard synchronous communications characters in bus organized systems such as the F6800 Microprocessor systems.

The bus interface of the F6852 includes Select, Enable, Read/Write, Interrupt, and bus interface logic to allow data transfer over an 8-bit bi-directional data bus. The parallel data of the bus system is serially transmitted and received by the synchronous data interface with synchronization, fill character insertion/deletion, and error checking. The functional configuration of the SSDA is programmed via the data bus during system initialization. Programmable control registers provide control for variable word lengths, transmit control, receive control, synchronization control, and interrupt control. Status, timing and control lines provide peripheral or modem control.

Typical applications include floppy disk controllers, cassette or cartridge tape controllers, data communications terminals, and numerical control systems.

- PROGRAMMABLE INTERRUPTS FROM TRANSMITTER, RECEIVER, AND ERROR DETECTION LOGIC
- CHARACTER SYNCHRONIZATION ON ONE OR TWO SYNC CODES
- EXTERNAL SYNCHRONIZATION AVAILABLE FOR PARALLEL-SERIAL OPERATION
- PROGRAMMABLE SYNC CODE REGISTER
- UP TO 600 KBPS TRANSMISSION
- PERIPHERAL/MODEM CONTROL FUNCTIONS
- THREE BYTES OF FIFO BUFFERING ON BOTH TRANSMIT AND RECEIVE
- SEVEN, EIGHT, OR NINE BIT TRANSMISSION
- OPTIONAL EVEN AND ODD PARITY
- PARITY, OVERRUN, AND UNDERFLOW STATUS



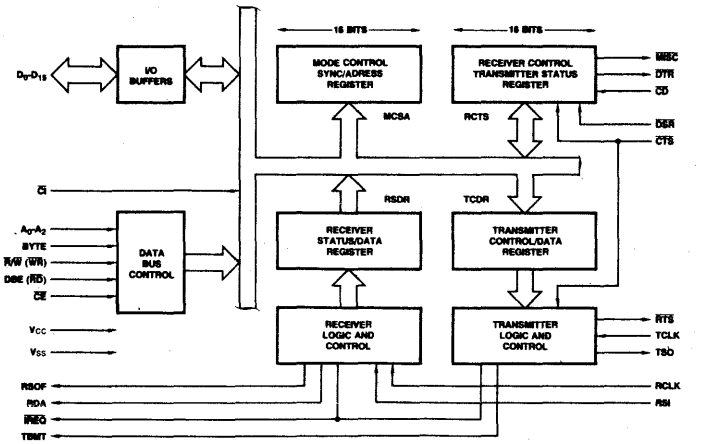
VCC = Pin 12
VSS = Pin 1

F6852 SSDA

F6854 ADVANCED DATA LINE CONTROLLER (ADLC)

GENERAL DESCRIPTION—The F6854/F68A54 ADLC perform the complex MPU/data communication link function for the Advanced Data Communication Control Procedure (ADCCP), High Level Data Link Control (HDLC) and Synchronous Data Link Control (SDLC) standards. The ADLC provides key interface requirements with improved software efficiency. The ADLC is designed to provide the data communications interface for both primary and secondary stations in stand alone, polling and loop configurations.

- F6800 COMPATIBLE
- PROTOCOL FEATURES
  - AUTOMATIC FLAG DETECTION AND SYNCHRONIZATION
  - ZERO INSERTION AND DELETION
  - AUTOMATIC ADDRESS FIELD EXTENSION (OPTIONAL)
  - EXTENDED CONTROL FIELD (OPTIONAL)
  - AUTO EXTENDABLE LOGIC CONTROL FIELD (OPTIONAL)
  - VARIABLE WORD LENGTH INFO FIELD—5, 6, 7, OR 8-BIT
  - AUTOMATIC FRAME CHECK SEQUENCE GENERATION AND CHECK
  - ABORT DETECTION AND TRANSMISSION
  - IDLE DETECTION AND TRANSMISSION
- MODEM/DATA CHANNEL CONTROL LINES
- LOOP MODE
- SINGLE 5 V POWER SUPPLY
- ENHANCED SPEED OPTION—F68A54



F6854 ADLC

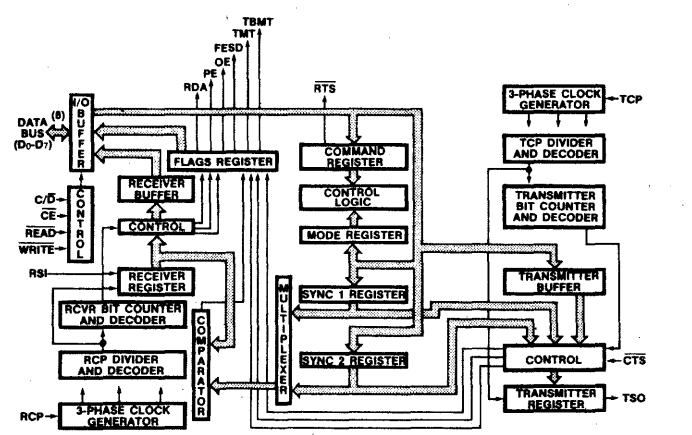
F6856 SYNCHRONOUS PROTOCOL COMMUNICATIONS CONTROLLER (SPCC)

DESCRIPTION — The F3846/F6856 Synchronous Protocol Communications Controller (SPCC) is a monolithic n-channel MOS-LSI circuit designed to satisfy the major interface requirements for Bit Oriented (BOP) and Byte Control Protocols (BCP). The SPCC converts parallel data from the CPU to a continuous serial data stream for transmission. Simultaneously, it converts received serial data to parallel data for the CPU. The SPCC is organized to interface with either an 8 or 16-bit bi-directional data bus, is fully TTL compatible and operates from a single +5 V suppyl.

- F6800 AND 8080 BUS COMPATIBLE
- DC TO 1M BPS DATA RATE
- LINE CONTROL PROTOCOLS
  - BIT ORIENTED PROTOCOLS (BOP): SDLC, ADCCP, HDLC
  - BYTE CONTROL PROTOCOLS (BCP): BISYNC, DDCMP AND OTHER BCP
- BIT ORIENTED PROTOCOLS
  - AUTOMATIC DETECTION AND GENERATION OF SPECIAL CONTROL SEQUENCES, i.e., FLAG, ABORT, GO-AHEAD
  - ZERO INSERTION AND DELETION
  - PRIMARY OR SECONDARY STATION SELECT
  - GLOBAL ADDRESS
  - AUTOMATIC EXTENDED ADDRESS
  - ONE OR TWO CONTROL BYTES
  - DATA CHARACTER LENGTH OF 5 TO 8-BITS WITH 1 TO 8-BIT RESIDUAL LAST CHARACTER
  - CCITT-CRC ERROR DETECTION
  - IBM RETAIL STORE LOOP MODE
- BYTE CONTROL PROTOCOL – BISYNC
  - SPECIAL CHARACTER GENERATION: DLE, SYNC
  - SPECIAL CHARACTER DETECTION: DLE, SYNC, SOH, STX, ITB, ETB, ETX
  - USASCII OR EBCDIC
  - NON-TRANSPARENT MODE AND TRANSPARENT MODE
  - 8-BIT CHARACTER LENGTH
  - AUTOMATIC FILL CHARACTER INSERTION WITH SELECTABLE STRIPPING
  - CCITT OR CRC-16 ERROR DETECTION
- BYTE CONTROL PROTOCOLS – DDCMP AND OTHER
  - PROGRAMMABLE SYNC CHARACTERS
  - 5 TO 8-BIT CHARACTER LENGTH
  - SELECTABLE CRC ERROR DETECTION
  - AUTOMATIC FILL CHARACTER INSERTION WITH SELECTABLE STRIPPING
- DIRECTLY ADDRESSABLE PARAMETER CONTROL REGISTERS: MODE, SYNC/ADDRESS, TRANSMITTER CONTROL AND RECEIVER CONTROL
- SEPARATE ADDRESSABLE STATUS AND DATA REGISTERS FOR RECEIVER AND TRANSMITTER
- MODEM HANDSHAKE SIGNALS: $\overline{RTS}$, $\overline{CTS}$, DTR, $\overline{DSR}$ AND CARRIER DETECT ($\overline{CD}$)
- NRZ OR NRZI (ZERO COMPLIMENTING)
- FULL OR HALF DUPLEX OPERATION
- SELF TEST LOOP MODE
- 8 OR 16-BIT BI-DIRECTIONAL 3-STATE DATA BUS
- TTL COMPATIBLE
- SINGLE +5 V SUPPLY
- 40-PIN PACKAGE

F6856 SPCC

F3843 UNIVERSAL SYNCHRONOUS ASYNCHRONOUS RECEIVER TRANSMITTER (USART)



GENERAL DESCRIPTION—The F3843 is a programmable, full duplex Universal Synchronous or Asynchronous Receiver and Transmitter (USART) designed for use in data communications systems. This device provides the interface between the bus-oriented format of the controller and the serial format of the peripheral unit. The programming inputs of the USART determine the transmission mode, character length, framing format, parity mode and baud rate.

The F3843 is manufactured with the n-channel Isoplanar silicon gate process, and is available in both plastic and ceramic 28-pin dual in-line packages as well as in commercial and military temperature ranges.

- 5, 6, 7, or 8-BIT SELECTABLE CHARACTER LENGTH
- ODD OR EVEN PARITY GENERATION AND CHECKING
- SELECTED NUMBER OF STOP BITS (1, 1 1/2, 2) IN ASYNCHRONOUS MODE
- SEPARATE RECEIVER AND TRANSMITTER CLOCKS
- SELECTABLE CLOCK RATES (16x, 32x, or 64x BAUD RATES)
- STATIC OPERATION—NO MINIMUM FREQUENCY
- MAXIMUM BAUD RATES: (3843-1DC)

  1x CLOCK (SYNC MODE) - 320K BAUD
  16x CLOCK (ASYNC MODE) - 20K BAUD
  32x CLOCK (ASYNC MODE) - 10K BAUD
  64x CLOCK (ASYNC MODE) - 5K BAUD

- ERROR FLAGS: OVERRUN, PARITY, AND FRAMING ERRORS
- HARDWARE AND SOFTWARE STATUS FLAGS FOR BOTH RECEIVER AND TRANSMITTER STATUS
- DOUBLE BUFFERED, FULL DUPLEX OPERATION
- EXTERNAL OR INTERNAL (ONE OR TWO SYNC WORDS) SYNCHRONIZATION
- TTL COMPATIBLE INPUTS AND OUTPUTS
- 3-STATE DATA BUS WITH OR-TIE CAPABILITY

F3843 USART

BIPOLAR MICROCOMPUTER PRODUCTS

The Fairchild line of bipolar microcomputer products includes the established 9400 4-Bit LSTTL/I^3L family and the F2900 4-Bit LSTTL family. These components, when used in microprogrammed controller/computer applications, offer the benefits of MSI/LSI and microprogramming.

The 9400 family consists of two sub-groups:

1. Devices produced for dedicated peripheral systems such as 9401/411 Cyclic Redundancy Checker/Generator and the 9403/9423 Serial-Parallel high speed FIFO.
2. Devices for microprogrammed controller applications Data Path Switch/ALRS and the I^3L 9408 Microprogram Sequencer.

4-BIT BIPOLAR MICROPROCESSOR FAMILY

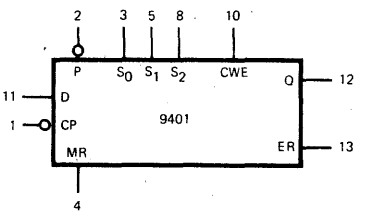
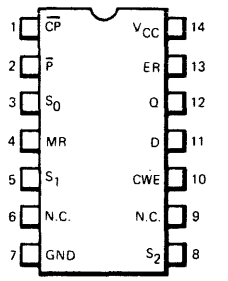
9401



CRC GENERATOR/CHECKER

FAIRCHILD TTL MACROLOGIC

DESCRIPTION - The 9401 Cycle Redundancy Check (CRC) Generator/Checker provides an advanced tool for implementing the most widely used error detection scheme in serial digital data handling systems. A 3-bit control input selects one-of-eight generator polynomials. The list of polynomials includes CRC-16 and CRC-CCITT as well as their reciprocals (reverse polynomials). Automatic right justification is incorporated for polynomials of degree less than 16. Separate clear and preset inputs are provided for floppy disc and other applications. The Error output indicates whether or not a transmission error has occurred. Another control input inhibits feedback during check word transmission. The 9401 is fully compatible with all TTL families.



- **GUARANTEED 10 MHz DATA RATE**
- **EIGHT SELECTABLE POLYNOMIALS**
- **ERROR INDICATOR**
- **SEPARATE PRESET AND CLEAR CONTROLS**
- **AUTOMATIC RIGHT JUSTIFICATION**
- **FULLY COMPATIBLE WITH ALL TTL LOGIC FAMILIES**
- **14-PIN PACKAGE**
- **TYPICAL APPLICATIONS:**
  - **FLOPPY AND OTHER DISC STORAGE SYSTEMS**
  - **DIGITAL CASSETTE AND CARTRIDGE SYSTEMS**
  - **DATA COMMUNICATION SYSTEMS**

©IC MASTER 1979

FUNCTIONAL DESCRIPTION – The 9401 is a 16-bit programmable device which operates on serial data streams and provides a means of detecting transmission errors. Cyclic encoding and decoding schemes for error detection are based on polynomial manipulation in modulo arithmetic. For encoding, the data stream (message polynomial) is divided by a selected polynomial. This division results in a remainder which is appended to the message as check bits. For error checking, the bit stream containing both data and check bits is divided by the same selected polynomial. If there are no detectable errors, this division results in a zero remainder. Although it is possible to choose many generating polynomials of a given degree, standards exist that specify a small number of useful polynomials. The 9401 implements the polynomials listed in *Table 1* by applying the appropriate logic levels to the select pins S_0, S_1 and S_2.

The 9401 consists of a 16-bit register, a Read Only Memory (ROM) and associated control circuitry as shown in the block diagram. The polynomial control code presented at inputs S_0, S_1 and S_2 is decoded by the ROM, selecting the desired polynomial by establishing shift mode operation on the register with Exclusive OR gates at appropriate inputs. To generate the check bits, the data stream is entered via the Data inputs (D), using the HIGH-to-LOW transition of the Clock input ($\overline{CP}$). This data is gated with the most significant output (Q) of the register, and controls the Exclusive OR gates *(Figure 1)*. The Check Word Enable (CWE) must be held HIGH while the data is being entered. After the last data bit is entered, the CWE is brought LOW and the check bits are shifted out of the register and appended to the data bits using external gating *(Figure 2)*.

To check an incoming message for errors, both the data and check bits are entered through the D input with the CWE input held HIGH. The 9401 is not in the data path, but only monitors the message. The Error Output becomes valid after the last check bit has been entered into the 9401 by a HIGH-to-LOW transition of $\overline{CP}$. If no detectable errors have occurred during the data transmission, the resultant internal register bits are all LOW and the Error Output (ER) is LOW. If a detectable error has occurred, ER is HIGH.

A HIGH on the Master Reset input (MR) asynchronously clears the register. A LOW on the Preset input ($\overline{P}$) asynchronously sets the entire register if the control code inputs specify a 16-bit polynomial; in the case of 12 or 8-bit check polynomials only the most significant 12 or 8 register bits are set and the remaining bits are cleared.

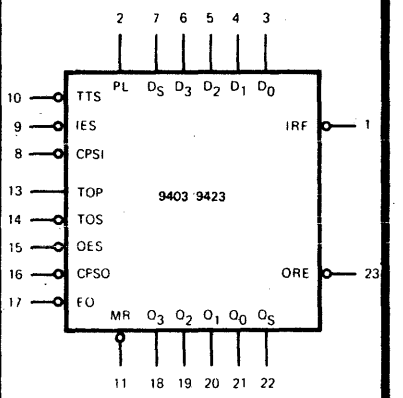
9403/9423

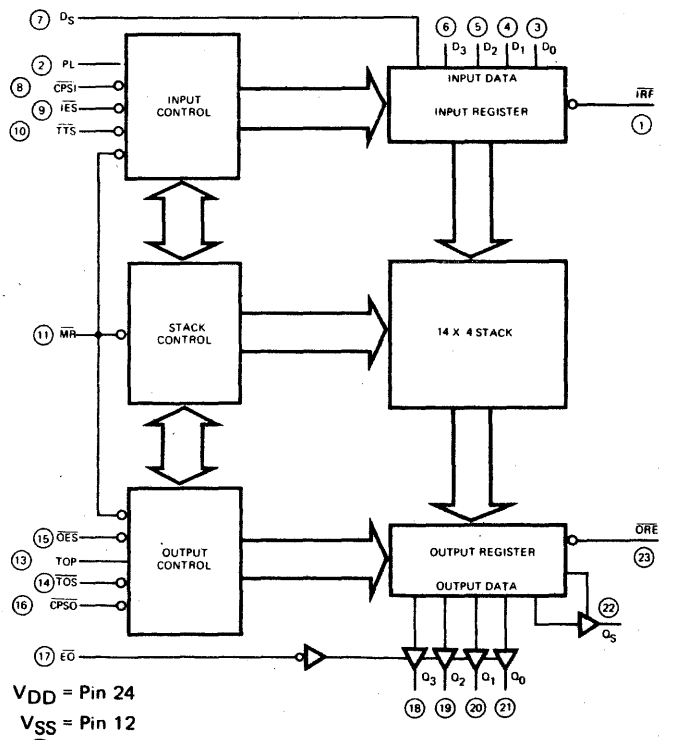
FIRST-IN FIRST-OUT (FIFO) BUFFER MEMORY



FAIRCHILD TTL MACROLOGIC

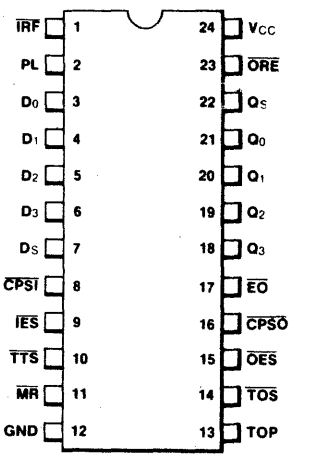
DESCRIPTION - The 9403/9423 is an expandable fall-through type high-speed First-In First-Out (FIFO) Buffer Memory optimized for high speed disc or tape controllers and communication buffer applications. It is organized as 16 or 64 words by four bits and may be expanded to any number of words or any number of bits (in multiples of four). Data may be entered or extracted asynchronously in serial or parallel, allowing economical implementation of buffer memories.

The 9403/9423 has 3-state outputs which provide added versatility and is fully compatible with all TTL families.



- 10 MHz SERIAL OR PARALLEL DATA RATE
- SERIAL OR PARALLEL INPUT
- SERIAL OR PARALLEL OUTPUT
- EXPANDABLE WITHOUT EXTERNAL LOGIC
- 3-STATE OUTPUTS
- FULLY COMPATIBLE WITH ALL TTL FAMILIES
- SLIM 24-PIN PACKAGE

LOGIC SYMBOL



V_{CC} = Pin 24
GND = Pin 12

BLOCK DIAGRAM

PIN NAMES

PIN NAME	DESCRIPTION	COMMENTS
$D_0 - D_3$	Parallel Data Inputs	
D_S	Serial Data Input	
PL	Parallel Load Input	HIGH on PL enables $D_0 - D_3$. Not edge triggered. Ones catching.
$\overline{CPSI}$	Serial Input Clock	Edge triggered. Activates on falling edge.
$\overline{IES}$	Serial Input Enable	Enables serial and parallel input when LOW.
$\overline{TTS}$	Transfer to Stack Input	A LOW on this pin initiates fall through.
$\overline{OES}$	Serial Output Enable Input	Enables serial and parallel output when LOW.
$\overline{TOS}$	Transfer Out Serial Input	A LOW on this pin enables a word to be transferred from the stack to the output register. (TOP must be HIGH also for the transfer to occur). Not edge triggered.
TOP	Transfer Out Parallel Input	A HIGH on this pin enables a word to be transferred from the stack to the output register. ($\overline{TOS}$ must be LOW for the transfer to occur). Not edge triggered.
$\overline{MR}$	Master Reset	Active LOW.
$\overline{EO}$	Output Enable	Active LOW.
$\overline{CPSO}$	Serial Output Clock Input	Edge triggered. Activates on falling edge.
$Q_0 - Q_3$	Parallel Data Outputs	
Q_S	Serial Data Output	
$\overline{IRF}$	Input Register Full Output	LOW when input register is full (Note b).
$\overline{ORE}$	Output Register Empty Output	HIGH when output register contains valid data.

FUNCTIONAL DESCRIPTION - As shown in the block diagram the 9403/9423 consists of three sections:

1. An Input Register with parallel and serial data inputs as well as control inputs and outputs for input handshaking and expansion.
2. A 4-bit wide, 14 or 62 word deep fall-through stack with self-contained control logic.
3. An Output Register with parallel and serial data outputs as well as control inputs and outputs for output handshaking and expansion.

Since these three sections operate asynchronously and almost independently, they will be described separately below:

Input Register (Data Entry):
The Input Register can receive data in either bit-serial or in 4-bit parallel form. It stores this data until it is sent to the fall-through stack and generates the necessary status and control signals.

Figure 1 is a conceptual logic diagram of the input section. As described later, this 5-bit register is initialized by setting the F3 flip-flop and resetting the other flip-flops. The Q-output of the last flip-flop (FC) is brought out as the "Input Register Full" output ($\overline{IRF}$). After initialization this output is HIGH.

Parallel Entry - A HIGH on the PL input loads the $D_0 - D_3$ inputs into the $F_0 - F_3$ flip-flops and sets the FC flip-flop. This forces the $\overline{IRF}$ output LOW indicating that the input register is full. During parallel entry, the $\overline{CPSI}$ input must be LOW. If parallel expansion is not being implemented, $\overline{IES}$ must be LOW to establish row mastership (see Expansion section).

©IC MASTER 1979

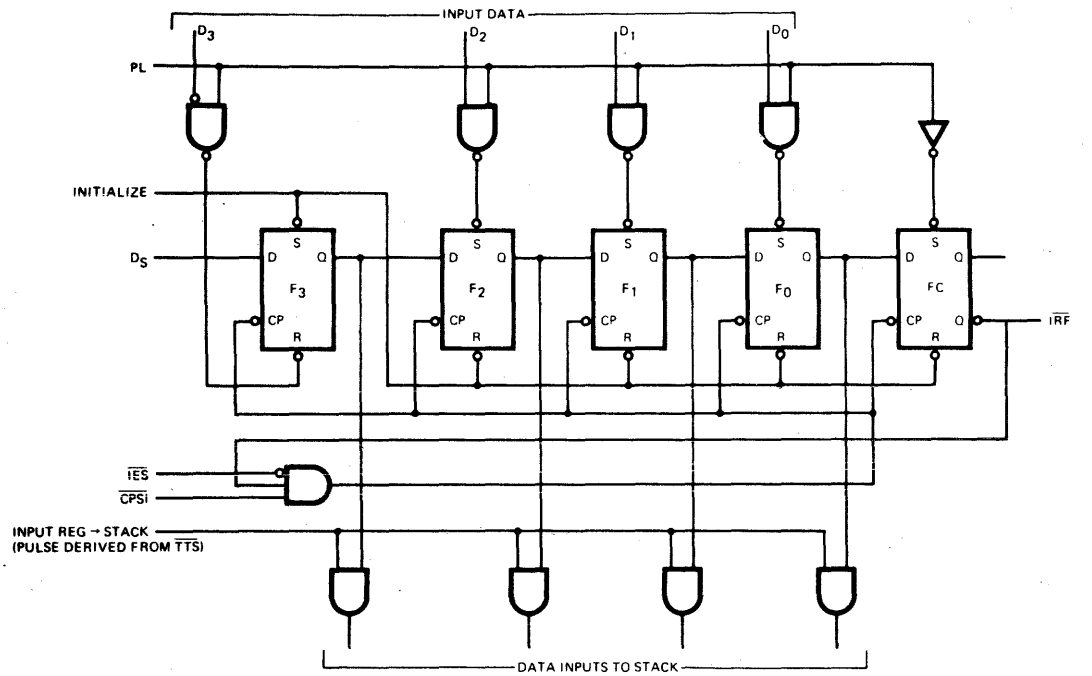

Fig. 1
CONCEPTUAL INPUT SECTION

Serial Entry - Data on the D_S input is serially entered into the F_3, F_2, F_1, F_0, FC shift register on each HIGH-to-LOW transition of the CPSI clock input, provided IES and PL are LOW.

After the fourth clock transition, the four data bits located in the four flip-flops F_0 - F_3. The FC flip-flop is set, forcing the $\overline{IRF}$ output LOW and internally inhibiting $\overline{CPSI}$ clock pulses from effecting the register. *Figure 2* illustrates the final positions in a 9403 resulting from a 64-bit serial bit train. B_0 is the first bit, B_{63} the last bit. Similar operation can be developed for 9423.

Transfer to the Stack -The outputs of Flip-Flops F_0 - F_3 feed the stack. A LOW level on the $\overline{TTS}$ input initiates a "fall-through" action. If the top location of the stack is empty, data is loaded into the stack and the input register is re-initialized. Note that this initialization is postponed until PL is LOW again. Thus, automatic FIFO action is achieved by connecting the $\overline{IRF}$ output to the $\overline{TTS}$ input.

An RS Flip-Flop (the Request Initialization Flip-Flop shown in *Figure 10*) in the control section records the fact that data has been transferred to the stack. This prevents multiple entry of the same word into the stack despite the fact the $\overline{IRF}$ and $\overline{TTS}$ may still be LOW. The Request Initialization Flip-Flop is not cleared until PL goes LOW. Once in the stack, data falls through the stack automatically, pausing only when it is necessary to wait for an empty next location. In the 9403, as in most modern FIFO designs, the $\overline{MR}$ input only initializes the stack control section and does not clear the data.

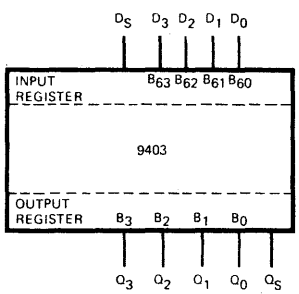

Fig. 2
FINAL POSITIONS IN A 9403 RESULTING FROM A 64-BIT SERIAL TRAIN

©IC MASTER 1979

Output Register (Data Extraction) – The Output Register receives 4-bit data words from the bottom stack location, stores it and outputs data on a 3-state 4-bit parallel data bus or on a 3-state serial data bus. The output section generates and receives the necessary status and control signals. *Figure 3* is a conceptual logic diagram of the output section.

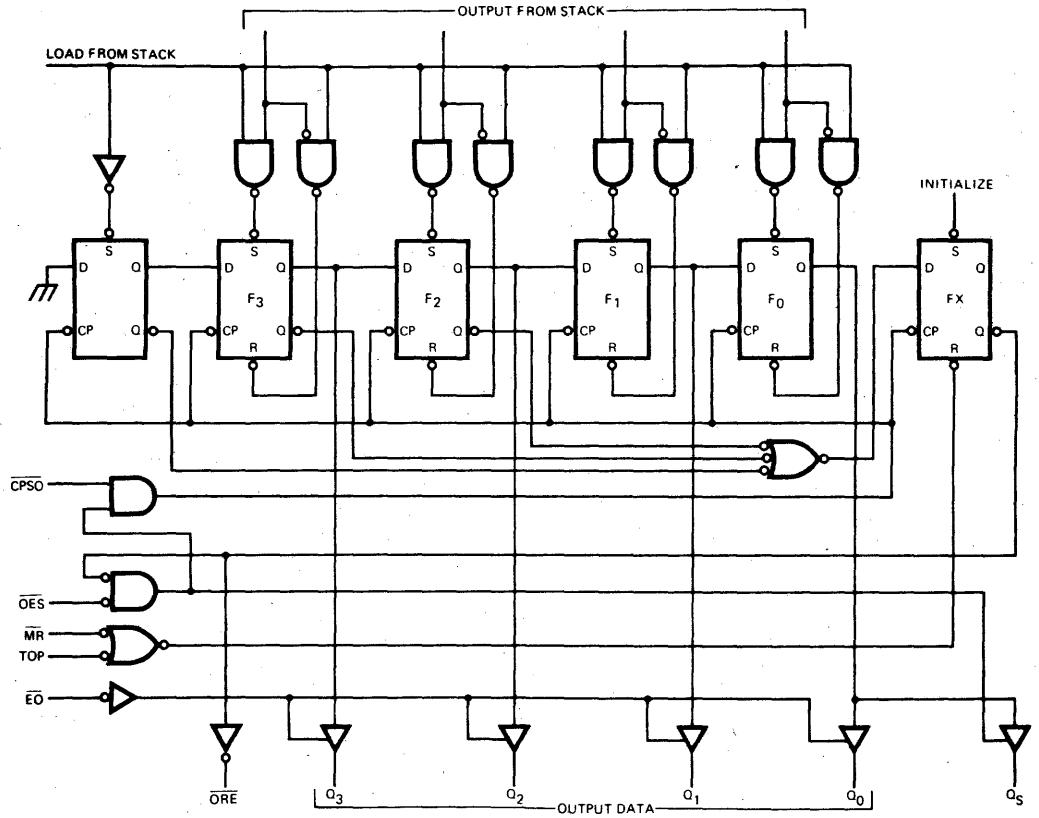

Fig. 3
CONCEPTUAL OUTPUT SECTION

Parallel Data Extraction – When the FIFO is empty after a LOW pulse is applied to $\overline{MR}$, the Output Register Empty ($\overline{ORE}$) output is LOW. After data has been entered into the FIFO and has fallen through to the bottom stack location, it is transferred into the Output Register provided the "Transfer Out Parallel" (TOP) input is HIGH. As a result of the data transfer $\overline{ORE}$ goes HIGH, indicating valid data on the data outputs (provided the 3-state buffer is enabled). TOP can now be used to clock out the next word. When TOP goes LOW, $\overline{ORE}$ will go LOW indicating that the output data has been extracted, but the data itself remains on the output bus until the next HIGH level at TOP permits the transfer of the next word (if available) into the Output Register. During parallel data extraction $\overline{CPSO}$ should be LOW. $\overline{TOS}$ should be grounded for single slice operation or connected to the appropriate $\overline{ORE}$ for expanded operation (see Expansion section).

TOP is not edge triggered. Therefore, if TOP goes HIGH before data is available from the stack, but data does become available before TOP goes LOW again, that data will be transferred into the Output Register. However, internal control circuitry prevents the same data from being transferred twice. If TOP goes HIGH and returns to LOW before data is available from the stack, ORE remains LOW indicating that there is no valid data at the outputs.

Serial Data Extraction – When the FIFO is empty after a LOW pulse is applied to $\overline{MR}$, the Output Register Empty ($\overline{ORE}$) output is LOW. After data has been entered into the FIFO and has fallen through to the bottom stack location, it is transferred into the Output Register provided $\overline{TOS}$ is LOW and TOP is HIGH. As a result of the data transfer $\overline{ORE}$ goes HIGH indicating valid data in the register. The 3-state Serial Data Output, Q_S, is automatically enabled and puts the first data bit on the output bus. Data is serially shifted out on the HIGH-to-LOW transition of $\overline{CPSO}$. To prevent false shifting, $\overline{CPSO}$ should be LOW when the new word is being loaded into the Output Register. The fourth transition empties the shift register, forces $\overline{ORE}$ output LOW and disables the serial output, Q_S (refer to *Figure 3*). For serial operation the $\overline{ORE}$ output may be tied to the $\overline{TOS}$ input, requesting a new word from the stack as soon as the previous one has been shifted out.

©IC MASTER 1979

Horizontal and Vertical Expansion - The 9403 and 9423 can be expanded in both the horizontal and vertical directions without any external parts and without sacrificing any of its FIFO's flexibility for serial/parallel input and output. The interconnections necessary to form a 31-word by 16-bit FIFO are shown in *Figure 4*. Using the same technique, any FIFO of (15m + 1) words by (4n) bits can be constructed, where m is the number of devices in a column and n is the number of devices in a row.

Figures 5 and *6* show the timing diagrams for serial data entry and extraction for the 31-word by 16-bit FIFO shown in *Figure 4*. The final position of data after serial insertion of 496 bits into the FIFO array of *Figure 4* is shown in *Figure 7*.

All applications shown for 9403 can be adapted to the 9423 with the depth of the stock being 64 locations rather than the 16 locations of 9403.

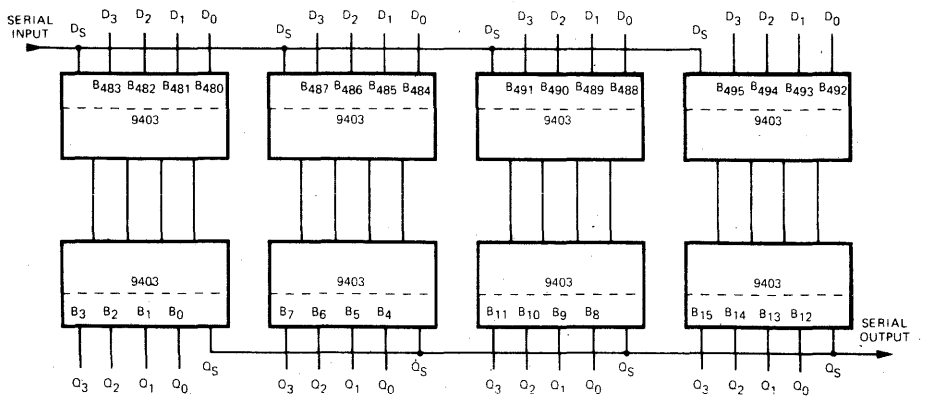

Fig. 7
FINAL POSITION OF A 496-BIT SERIAL INPUT

Interlocking Circuitry – Most conventional FIFO designs provide status signals analogous to $\overline{IRF}$ and $\overline{ORE}$. However, when these devices are operated in arrays, variations in unit to unit operating speed require external gating to assure all devices have completed an operation. The 9403 incorporates simple but effective "master/slave" interlocking circuitry to eliminate the need for external gating.

In the 9403 array of *Figure 4* devices 1 and 5 are defined as "row masters" and the other devices are slaves to the master in their row. No slave in a given row will initialize its Input Register until it has received LOW on its $\overline{IES}$ input from a row master or a slave of higher priority.

In a similar fashion, the $\overline{ORE}$ outputs of slaves will not go HIGH until their $\overline{OES}$ inputs have gone HIGH. This interlocking scheme ensures that new input data may be accepted by the array when the $\overline{IRF}$ output of the final slave in that row goes LOW and that output data for the array may be extracted when the $\overline{ORE}$ of the final slave in the output row goes HIGH.

The row master is established by connecting its $\overline{IES}$ input to ground while a slave receives its $\overline{IES}$ input from the $\overline{IRF}$ output of the next higher priority device. When an array of 9403 FIFOs is initialized with a LOW on the $\overline{MR}$ inputs of all devices, the $\overline{IRF}$ outputs of all devices will be HIGH. Thus, only the row master receives a LOW on the $\overline{IES}$ input during initialization. *Figure 8* is a conceptual logic diagram of the internal circuitry which determines master/slave operation. Whenever $\overline{MR}$ and $\overline{IES}$ are LOW, the Master Latch is set. Whenever $\overline{TTS}$ goes LOW the Request Initialization Flip-Flop will be set. If the Master Latch is HIGH, the Input Register will be immediately initialized and the Request Initialization Flip-Flop reset. If the Master Latch is reset, the Input Register is not initialized until $\overline{IES}$ goes LOW. In array operation, activating the $\overline{TTS}$ initiates a ripple input register initialization from the row master to the last slave.

A similar operation takes place for the output register. Either a $\overline{TOS}$ or TOP input initiates a load-from-stack operation and sets the ORE Request Flip-Flop. If the Master Latch is set, the last Output Register Flip-Flop is set and $\overline{ORE}$ goes HIGH. If the Master Latch is reset, the $\overline{ORE}$ output will be LOW until an $\overline{OES}$ input is received.

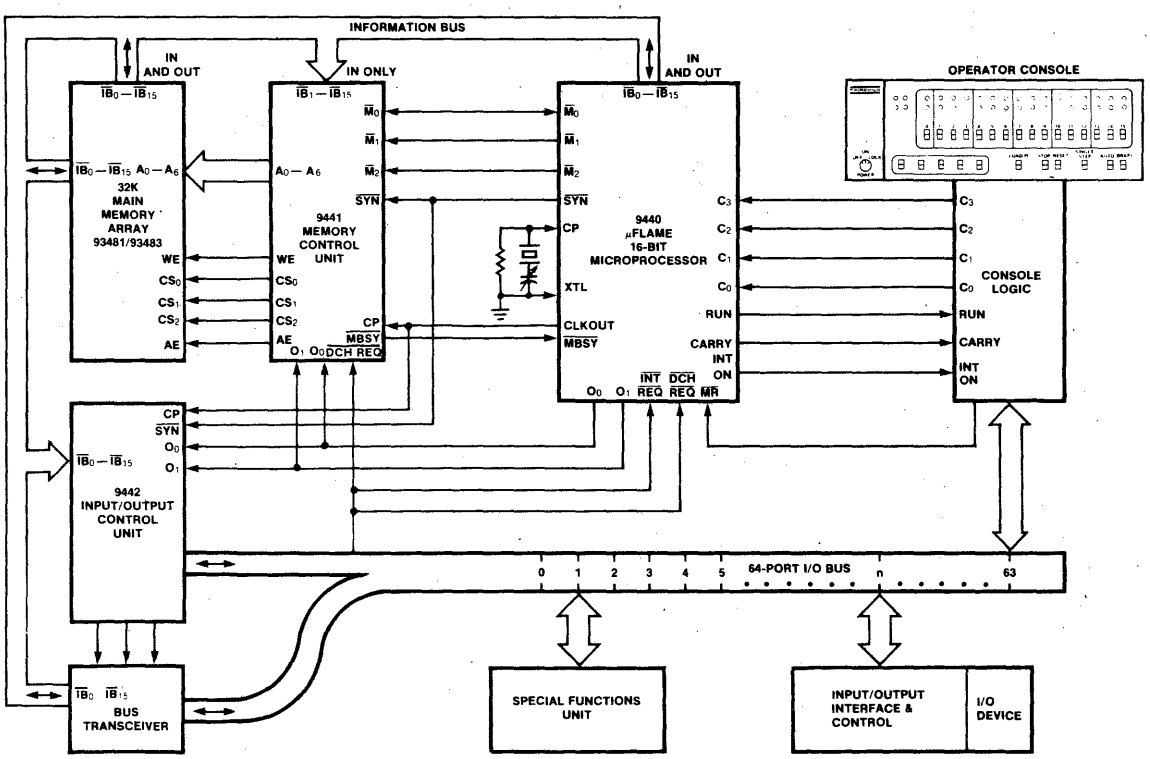
9440 MICROFLAME™
16-BIT BIPOLAR MICROPROCESSOR



GENERAL DESCRIPTION — The 9440 MICROFLAME single-chip 16-bit bipolar processor, packaged in a 40-pin DIP, is implemented using Fairchild's Isoplanar Integrated Injection Logic technology (I^3L™). Though structurally different from the CPUs of the Data General NOVA line of minicomputers, the 9440 offers comparable performance and executes the same instruction set.

- **EIGHT 16-BIT ON-CHIP REGISTERS**
- **64 DIRECTLY ADDRESSABLE I/O DEVICES, EACH WITH THREE BIDIRECTIONAL I/O PORTS**
- **PRIORITY INTERRUPT HANDLING WITH UP TO 16 PRIORITY LEVELS**
- **FAST DIRECT MEMORY ACCESS AT MEMORY SPEEDS**
- **16-BIT 3-STATE BIDIRECTIONAL INFORMATION BUS**
- **FLEXIBLE OPERATOR CONSOLE CONTROL USING ONLY FOUR LINES**
- **POWERFUL, WIDELY USED INSTRUCTION SET**
- **MULTIFUNCTION INSTRUCTIONS FOR EFFICIENT MEMORY USAGE**
- **FOUR CLASSES OF INSTRUCTIONS; TOTAL OF 2192 DIFFERENT INSTRUCTIONS**
- **EIGHT ADDRESSING MODES, 32K 16-BIT WORDS (64K BYTES) ADDRESSING RANGE**
- **5 V POWER SUPPLY**
- **TTL INPUTS AND OUTPUTS**
- **TYPICAL 1 W POWER DISSIPATION**
- **FULL MILITARY TEMPERATURE RANGE VERSION**
- **SINGLE-CLOCK STATIC OPERATION, ON-CHIP OSCILLATOR, DC TO 12 MHz CLOCK RATE**
- **COMPATIBLE HIGH SPEED MEMORIES AVAILABLE (93481/93483)**
- **TOTAL SOFTWARE WITH FIRE™ SOFTWARE PACKAGE**

FAIRCHILD

Fairchild MICROPROCESSOR

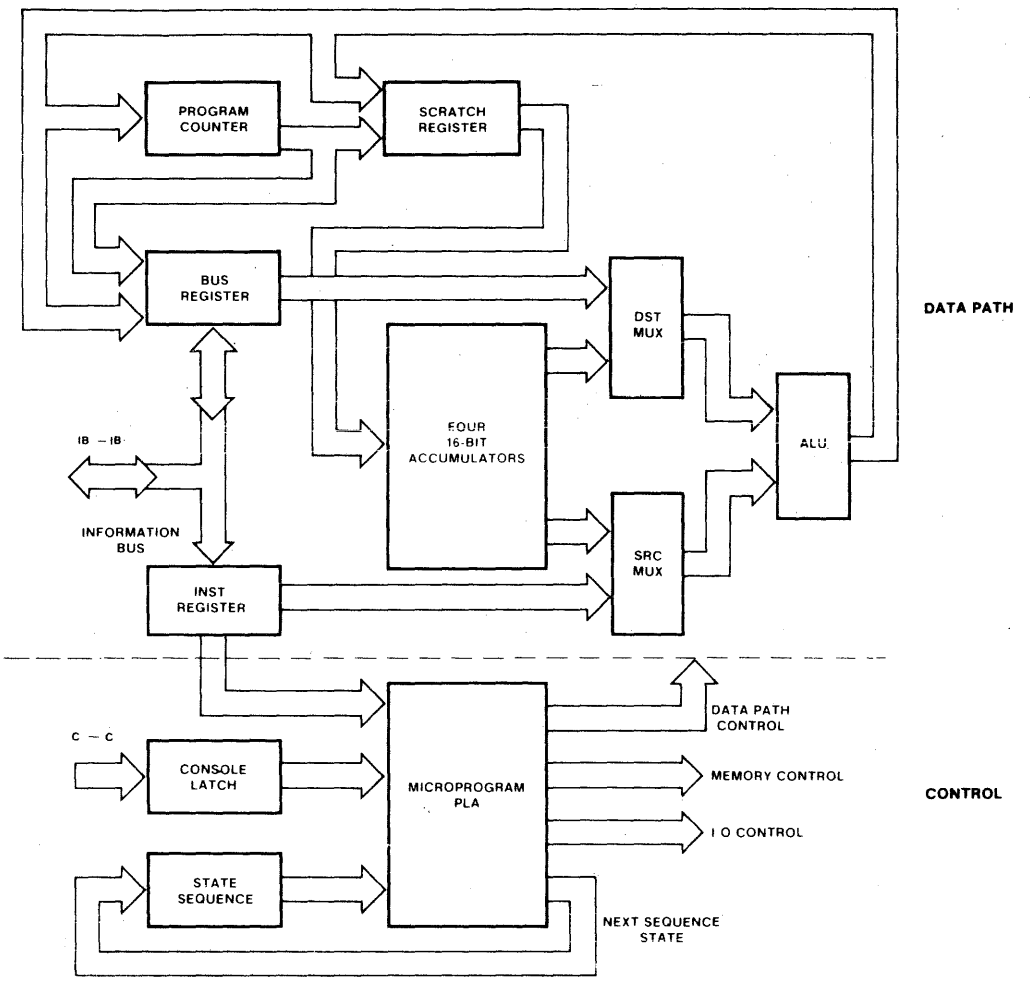

Fig. 1 9440 MICROFLAME CPU Block Diagram

9440 ARCHITECTURE *(Figure 1)*
The 9440 single-chip 16-bit bipolar processor, packaged in a 40-pin DIP, is implemented using Fairchild's Isoplanar Integrated Injection Logic technology (I3L.™). Though structurally different from the CPUs of the NOVA line of minicomputers, the 9440, as a microprocessor, offers comparable performance and executes the same instruction set.

The processor is a stored program machine using homogeneous external memory, i.e., instructions and data are stored in the same memory. Although the processor handles 16 bits of information, only 15 bits are used for addressing the memory. Thus, the intrinsic memory capacity of a 9440 system is 32,768 16-bit words.

The 9440 consists of a collection of data paths and all the necessary control circuitry. It governs peripheral I/O equipment, performs the arithmetic, logic and data handling operations and sequences the program.

Data Paths — The data path portion includes a bank of four 16-bit general-purpose registers (accumulators AC0 - AC3), two multiplexers, an ALU, and four 16-bit special registers — scratch register, bus register, instruction register and program counter. Internal data flows between the various registers via 4-bit-wide data paths.

©IC MASTER 1979

The accumulators store the operands required for all arithmetic/logic operations. Accumulators AC2 and AC3 are also used as index registers and AC3 serves as the subroutine linkage register as well. All input-output data transfers take place through the accumulators; however, a word in a memory location may be incremented or decremented without accumulator participation. Data can be moved in either direction between the memory and any accumulator.

The destination and source multiplexers are connected to all four accumulators and select source and destination registers for each operation. The multiplexers also receive other inputs from the bus and instruction registers, which permit the ALU to be used for effective-address calculations and other purposes.

The ALU is four bits wide and operates on two 16-bit words in four consecutive steps, taking one 4-bit nibble per step. By adding the associated Carry bit to the 16-bit result from the ALU, a 17-bit word is formed which may be rotated either left or right.

Data from the ALU to the destination accumulator is held in the scratch register for one cycle. The bus register is connected to the bidirectional information bus and can either supply or receive 16 bits of data in parallel. The instruction register is loaded with 16 bits in parallel, directly from the information bus during an instruction-fetch operation. The 15-bit program counter determines the sequence in which instructions are executed. It is incremented to take instructions from consecutive locations and the instruction sequence can be altered at any time by changing the PC contents (jump-class instruction) or by incrementing PC twice (skip-class instruction).

Control — Control signals are supplied to the data path by the internal mask-programmed logic arrray (PLA). For each of 72 different data-path operations, there is a 24-bit output word in the PLA selected according to the combination of 19 input lines. These are defined in *Figure 2*.

The 9440 operates with an on-chip oscillator when a crystal is tied between CP and XTL or it can be driven by an external oscillator via the CP input. The on-chip clock logic circuit generates the internal clock signal, a synchronization signal ($\overline{SYN}$), and several other timing pulses.

A macro-instruction in the 9440 consists of several microcycles, each with a corresponding one-of-16 sequence-control state. Each microcycle consists of several phases, or nanocycles, four of which are devoted to controlling the data-path circuitry. During each of these phases, the data path circuitry operates on a 4-bit nibble out of the 16 bits of the operands and clocks its various registers at half the oscillator rate. Another phase provides the time delay required for a new output word of the PLA to become valid after the PLA inputs are changed.

The bus register and the instruction register are loaded from the information bus at different times during the execution cycle.

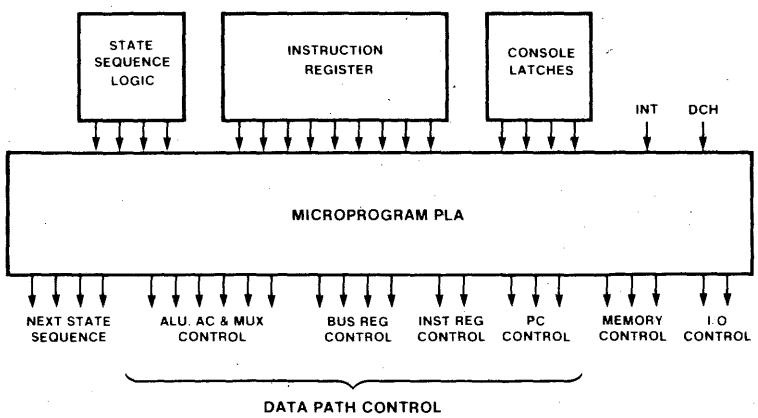

Fig. 2 Programmed Logic Array

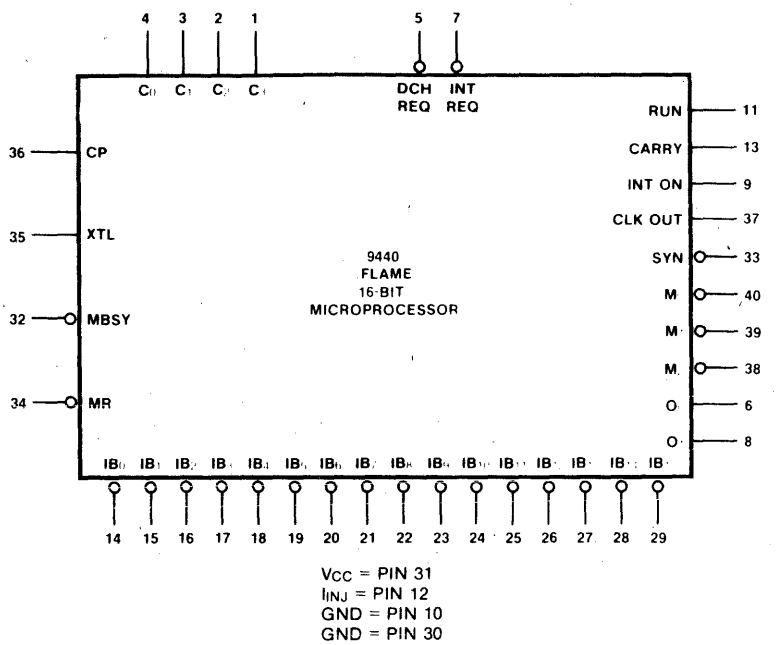

Fig. 3 Logic Symbol

9440 SIGNAL DESCRIPTIONS *(Figure 3)*

Information Bus — $\overline{IB}_0$-$\overline{IB}_{15}$ (Inputs/Outputs) — The 16-bit bidirectional 3-state information bus is used to transfer address, data and instruction information between the processor and main memory, and to transfer data and control information to and from I/O devices. A LOW level defines a binary '1'.

Status Lines — RUN, CARRY, INT ON — These lines are used to convey the status information of the processor mainly for display on an operator console.

RUN (Output) — A HIGH level on this line indicates that the 9440 is not in the WAIT state and is executing instructions or performing console operations.

CARRY (Output) — Shows the current status of the 9440 Carry flip-flop. A HIGH level is a binary '1'.

INT ON (Output) — Shows the state of the 9440 Interrupt Enable flip-flop. A HIGH level indicates that the 9440 is enabled to accept interrupts.

Operator Console Control — C_0-C_3, $\overline{MR}$ — Using the operator console, a special I/O device, the operator controls 9440 operation via the four C lines and the Master Reset line.

C_0-C_3 (Inputs) — The various console operations are coded on the Control lines as shown below. These lines must be active long enough for the 9440 to respond to the command and indicated by RUN going to the high state, and should be disabled immediately thereafter.

$\overline{MR}$ (Input) — When a LOW level is applied to Master Reset, the 9440 halts immediately and goes to a wait state. All internal registers are unaffected. The Interrupt-Enable flip-flop is cleared.

Input/Output Control — O_0-O_1, $\overline{INT\ REQ}$, $\overline{DCH\ REQ}$ — I/O devices communicate with the 9440 through the common information bus under either program or interrupt control. Also, high-speed devices can gain access to main memory via the data channel (DMA mode).

O_0, O_1 (Outputs) — To avoid conflicts on the information bus, the I/O devices are sent synchonization signals. A code, defining one of four functions, is conveyed to each I/O device over O_0 and O_1, which are valid before and during $\overline{SYN}$.

Console-Operation Code

O_1	O_0	FUNCTION
L	L	Instruction Fetch
L	H	Data Channel Acknowledge
H	L	I/O Execute
H	H	No Operation

I/O-Device Code

$\overline{\text{INT REQ}}$ (Input) — The I/O devices can interrupt normal program flow by activating the Interrupt Request input. The 9440 recognizes an interrupt request at the end of the current instruction provided its Interrupt-Enable flip-flop is set.

$\overline{\text{DCH REQ}}$ (Input) — The I/O devices can gain direct access to the main memory by activating the Data Channel Request input. After the device is granted data channel access, it can control memory operation using the $\overline{M}_0$-$\overline{M}_2$ lines.

Of the four functions which can interrupt the normal flow if instruction execution, MASTER RESET ($\overline{\text{MR}}$) is the highest priority, followed in order by $\overline{\text{DCH REQ}}$, $\overline{\text{INT REQ}}$ and the Console HALT Command.

Memory Control — $\overline{M}_0$-$\overline{M}_2$, $\overline{\text{MBSY}}$ — The processor controls the main memory via the three open-collector Memory Control lines ($\overline{M}_0$-$\overline{M}_2$) and synchronizes itself to the memory cycle time indicated by the Memory-Busy ($\overline{\text{MBSY}}$) signal.

$\overline{M}_0$ (Input/Output) — A LOW level on $\overline{M}_0$ indicates a memory Read operation.

$\overline{M}_1$ (Input/Output) — A LOW level on $\overline{M}_1$ indicates a memory Write operation.

$\overline{M}_2$ (Input/Output) — A LOW level on $\overline{M}_2$ indicates that the memory address register must be loaded on or before the HIGH-to-LOW transition of $\overline{\text{SYN}}$.

During DMA operation, the 9440 is not driving the $\overline{M}$ lines. An external device can control memory by applying a LOW level on the appropriate $\overline{M}$ line.

$\overline{\text{MBSY}}$ (Input) — A LOW level on $\overline{\text{MBSY}}$ indicates a memory operation is in progress. When the 9440 starts a memory cycle, $\overline{\text{MBSY}}$ must be HIGH. If it is LOW, the processor clock logic will defer putting out $\overline{\text{SYN}}$ until $\overline{\text{MBSY}}$ becomes HIGH. For LD MAR or Write memory operations, the 9440 activates $\overline{\text{SYN}}$ and then waits for $\overline{\text{MBSY}}$ to respond with a LOW level. For a Read operation, the 9440 waits for $\overline{\text{MBSY}}$ to go LOW and back HIGH before it proceeds.

Timing — CP, XTL, CLK OUT, $\overline{\text{SYN}}$ —

CP (Input) — The 9440 can operate with an on-chip oscillator when a crystal is tied between CP and XTL or it can operate from an external clock (CP).

XTL (Input) — The XTL input is used only when operating with a crystal.

CLK OUT (Output) — The internal oscillator is available to the outside world on CLK OUT.

$\overline{\text{SYN}}$ (Output) — $\overline{\text{SYN}}$ is an active LOW synchronization signal for memory and I/O devices. It is activated once for each processor microcycle.

Power — V_{CC}, I_{INJ}, GND

V_{CC} requires 5 V, I_{INJ} requires 300 mA current source at 1.0 V.

©IC MASTER 1979

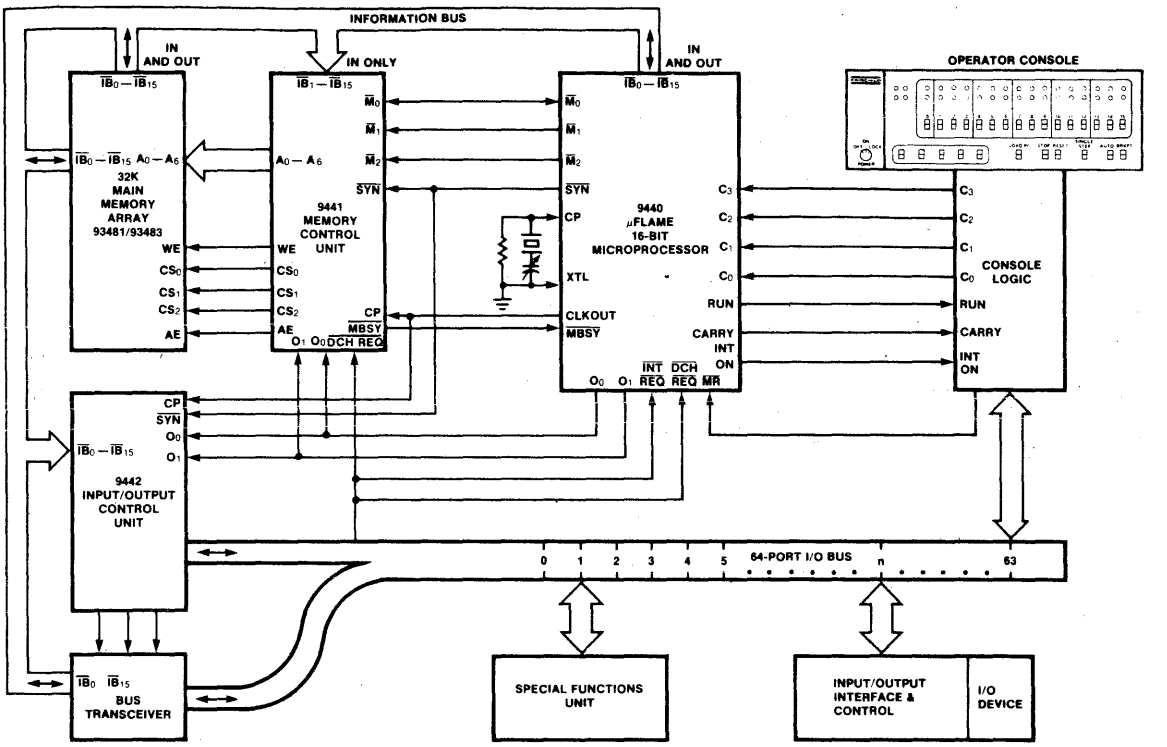

Fig. 4 9440 Microflame System

9440 SYSTEM

The 9440 CPU is a powerful machine that acts as the heart of a minicomputer-class microprocessor. However, to maximize performance, any CPU must be surrounded by support devices. A perfectly matched system can be built as shown in *Figure 4*.

Here, in addition to the 9440 CPU, the system contains the 9441 Memory Control Unit, the 9442 Input/Output Control Unit, the Special Functions Unit and an array of 93481 or 93483 I3L dynamic memories as follows:

9441 Memory Control Unit contains a 15 bit memory address register, refresh address counter and a 7-bit address multiplexer. It provides the timing and control signals to operate the I3L dynamic memory (93481, 93483) for read, write, refresh and DMA operations.

9442 Input/Output Control Unit responds to I/O instructions and generates the timing and control signals for 9440 peripheral devices.

93481 4K I3L bipolar dynamic memory. Single 5 V supply, 100 ns performance, compatible semiconductor memory.

93483 16K I3L bipolar dynamic memory. Single 5 V supply, 100 ns performance, compatible semiconductor memory.

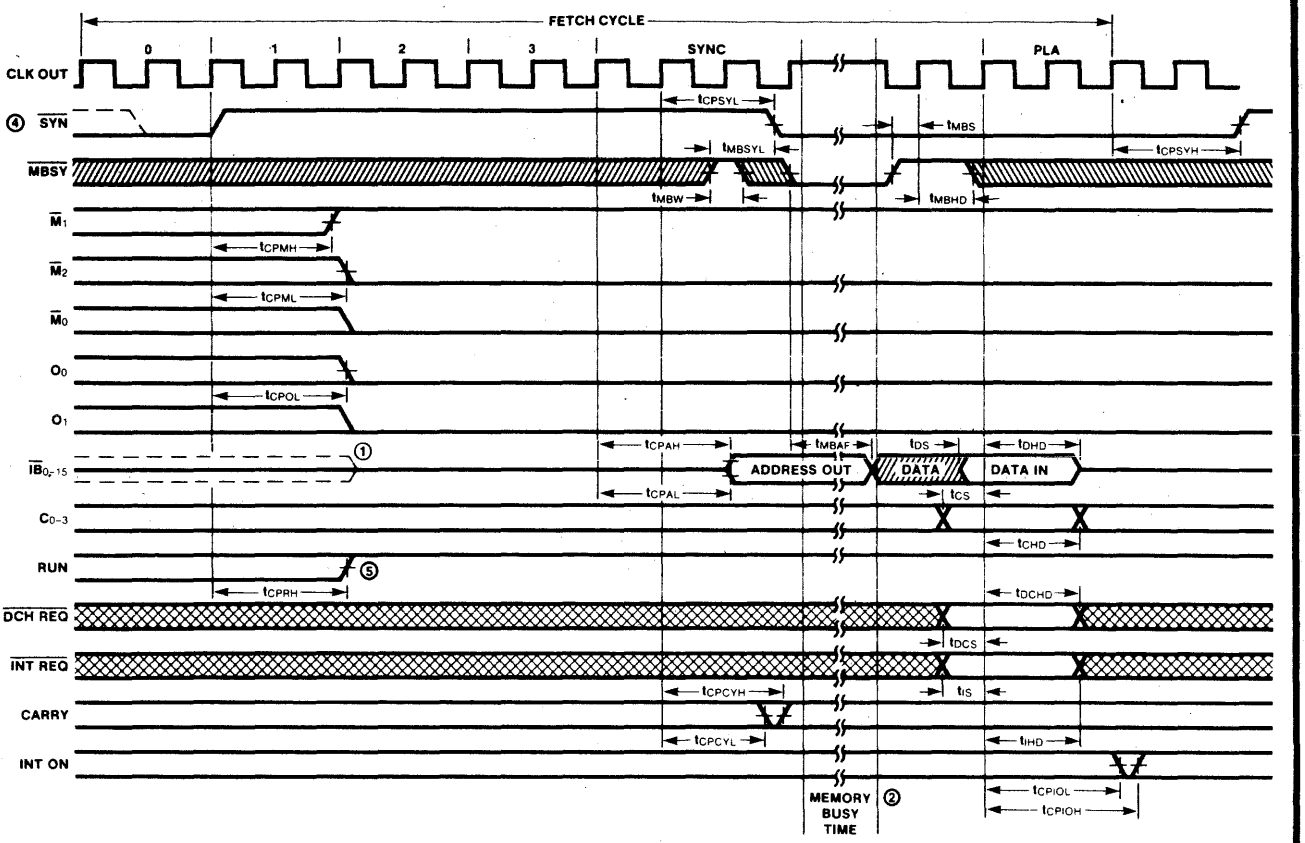

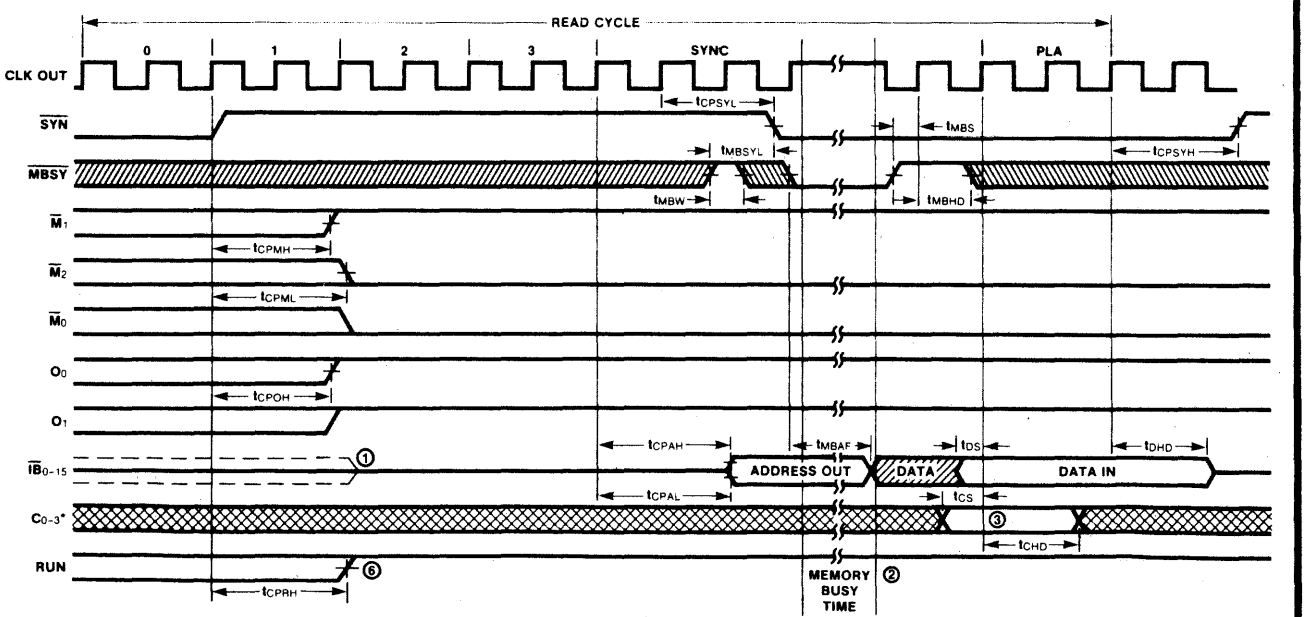

Fig. 5 Fetch Cycle

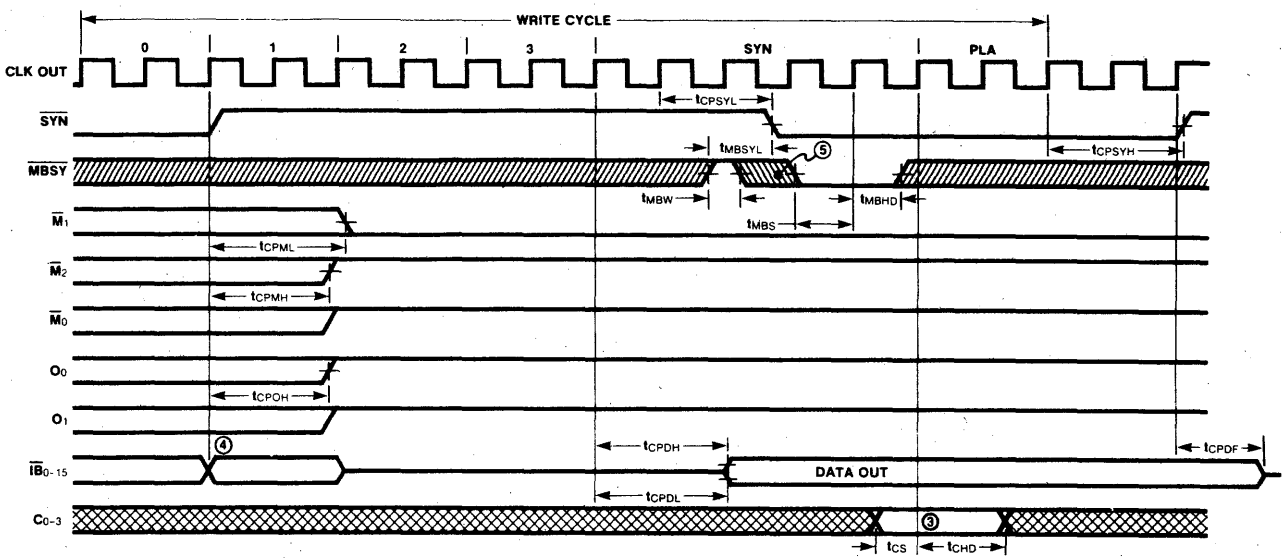
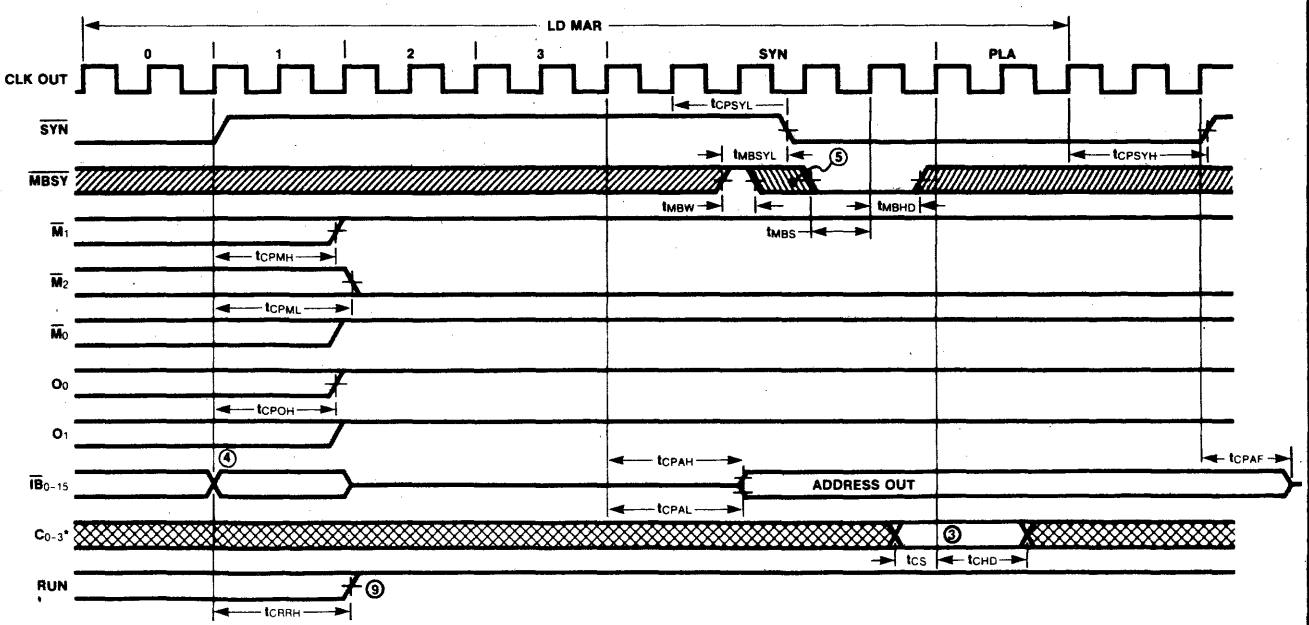


RUN, $\overline{\text{DCH REQ}}$, $\overline{\text{INT REQ}}$, CARRY, INT ON unaffected during this cycle.

Fig. 6 Read Cycle



©IC MASTER 1979

NOTES:
1. The Information Bus is driven as a result of the previous cycle.
2. The Fetch and Read cycles will be stretched out for slower memories.
3. Applies to console operation using this cycle type.
4. When the previous cycle was an I/O IN or I/O OUT cycle.
5. For a CONTINUE operation (#35 in the "9440 Instruction Execution" table on page 18).
6. For a LOAD PC, EXAMINE MEMORY or EXAMINE NEXT operations (#30, 31, 32 in the "9440 Instruction Execution" table on page 18).
7. The Information Bus is driven as a result of the previous cycle.
8. The 9440 waits for $\overline{MBSY}$ to go LOW. By holding $\overline{MBSY}$ HIGH, the user may idle the processor.
9. For DEPOSIT MEMORY or DEPOSIT NEXT operations (#33, 34 in the "9440 Instruction Execution" table on page 18).
10. For EXAMINE ACCUMULATOR or DEPOSIT ACCUMULATOR operations (#28, 29 in the "9440 Instruction Execution" table on page 18).

RUN, $\overline{DCH\ REQ}$, $\overline{INT\ REQ}$, CARRY, INT ON unaffected during this cycle.

Fig. 7 Write Cycle

$\overline{DCH\ REQ}$, $\overline{INT\ REQ}$, CARRY, INT ON unaffected during this cycle.

Fig. 8 Load Memory Address Register Cycle

©IC MASTER 1979

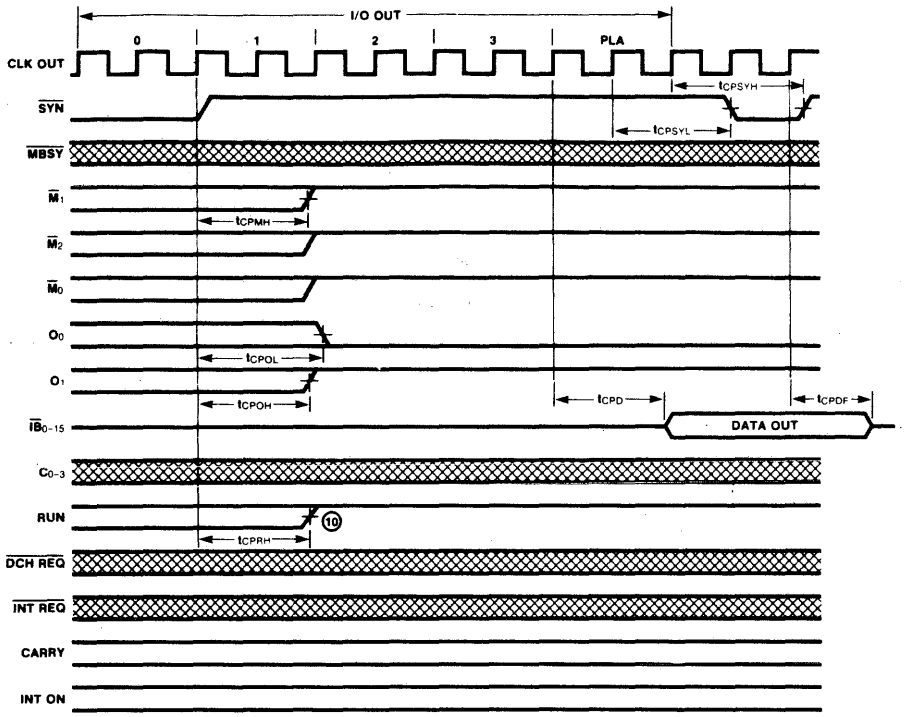


Fig. 9 I/O Out Cycle

NOTES:
11. During $\overline{DCH}$, the 9440 is not driving the $\overline{M}$ lines. An external device can control the memory when a LOW is applied to the appropriate $\overline{M}$ line.
12. The 9440 floats the $\overline{IB}_{0-15}$. The Information Bus is available to the I/O devices, the Console, and the memory as needed.
13. For all the CONSOLE operations (#28-35 in the "9440 Instruction Execution" table on page 18).
14. For CONSOLE operations (#28-34 in the "9440 Instruction Execution" table on page 18).

9440 INSTRUCTIONS

Memory Reference instructions without register are used for branching (JMP, JSR) without involving accumulators. These instructions are also used for modifying memory (ISZ, DSZ). Memory Reference instructions with register are used to move 16-bit words between the memory and the accumulators.

Arithmetic/Logic instructions perform arithmetic (ADD, ADC, INC, NEG, SUB) or Boolean (AND, COM, MOV) operations on the contents of two registers. The result of each operation together with the Carry bit can be rotated and tested for skip conditions as part of the same arithmetic/logic instruction; loading in the destination register is optional.

Input/Output instructions move data between the 9440 accumulators and three buffers in the peripheral device interface. These instructions also perform control functions in the I/O device and test the status flags in both the peripheral circuitry and the central processor.

©IC MASTER 1979

FAIRCHILD INTEGRATED REAL-TIME EXECUTIVE (FIRE) SOFTWARE

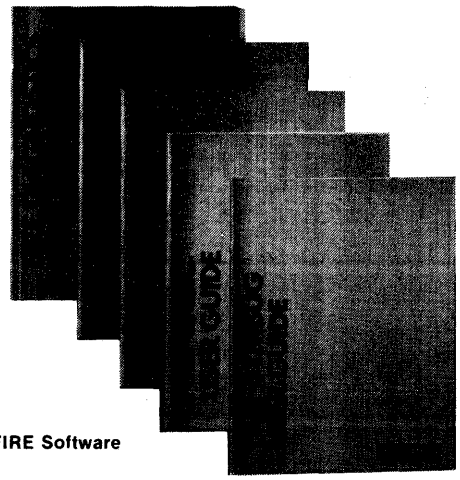
The instruction set resident in the 9440 MICROFLAME CPU will be familiar to those who have had experience with the NOVA instruction set. It consists of 2192 different instructions divided into four convenient classes — Memory Reference with or without register, Arithmetic/Logic, and Input/Output.

A comprehensive FIRE software system has been developed to thoroughly support the MICROFLAME-based products in a variety of applications. It includes programs that range from the simplest bootstrap and binary loaders (FIRE-LOAD) to the most sophisticated FIRE-FORTRAN and FIRE-IDOS. Also, a cross macro-assembler, a cross linking loader and a cross simulator debugger are available on a worldwide time-sharing basis for program development.

The basic software package, FIRE 1, includes FIRE-DIAGNOSTICS, FIRE-LOAD bootstrap and binary loaders and FIREBUG interactive assembler, debugger and editor. FIRE-DIAGNOSTICS programs, for trouble-shooting the FIRE family of products, consist of a Toggle-In Memory Address test and Memory Tester (FIRE-TOGGLE), an Instruction Timer (FIRE-TIMER), a System Exerciser (FIRE-EX), and Memory Diagnostic (FIRE-MEM).

FIRE-TOGGLE

The Toggle-In Memory Address test and the Memory Tester programs are each short enough (approximately 10 words) to enter via the console switches. The Memory Address test program tests the memory addressing by writing into the memory locations and reading each location on a second pass. The Memory Tester program performs a non-destructive memory test; that is, the original content of each word is restored after testing that the word may be written into the memory and read back.



These tests are normally used for two reasons. Firstly, they give a measure of confidence that the CPU and memory work. In this sense, they are useful for verifying that the system is functional after, for instance, swapping memory boards. Secondly, if the system fails, therefore precluding the loading of more advanced diagnostics, these tests can help to identify which device is at fault, the CPU,the memory or the I/O.

FIRE-TIMER

The FIRE-TIMER program is used to determine the instruction execution times. It uses the I/O terminal device as the standard with which to measure the times and to report the results. The instruction timer is most useful for detecting clock drift and for demonstration purposes.

FIRE-EX

The FIRE-EX System Exerciser program is the primary tool for testing and debugging the CPU, I/O terminal device (TTI and TTO), and high-speed paper tape reader and punch (PTR and PTP). In addition, most memory faults should be detected. The program performs and exhaustive test of the CPU's ability to perform all non-I/O instructions, then executes detailed tests on memory and each I/O device, and finally tests all I/O devices and memory simultaneously. Using the console switches, the operator determines the I/O devices to be tested and the testing sequences to be performed.

FIRE Software

FIRE-MEM

The FIRE-MEM Memory Diagnostic program is designed to thoroughly test the system main memory. The tests performed are the True/Complement Address test, the Checkerboard Test, the Walking Well test, and the Ping-Pong test. The console switches are used to select the tests to be performed and to control typing of error messages. The FIRE-MEM program moves around in the memory to test each area completely.

FIRE-LOAD

The FIRE-LOAD Bootstrap and Binary Loader program is used to load data from paper tapes into the memory in absolute binary format. Each record from the tape is read into a buffer and checksum checked before any data are stored. This prevents data from being stored in the wrong place due to a read error on the address word.

FIREBUG

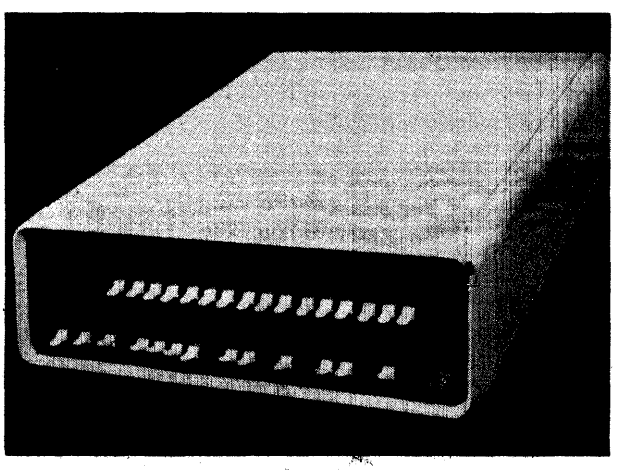
The FIREBUG Interactive Entry and Debugging program acts as a position-independent, stand-alone mini executive that is available on various media, including PROMs. With the PROM version of FIREBUG, the MICROFLAME-based system can be controlled without the usual operator console. FIREBUG is used to enter, modify, list, punch, load, assemble, disassemble, debug, and monitor symbolic assembly language programs. Debugging and monitoring of programs is greatly aided by the program's powerful multiple breakpoints and trace capabilities. The FIREBUG program is position-independent and can be moved to any available location after loading in main memory. All FIREBUG program operations can be performed from the terminal keyboard. Once FIREBUG software is loaded into the system, the computer console is no longer required. One can start and stop program execution, examine and modify all registers and memory locations without resort to front panel switches.

ADDITIONAL FIRE PROGRAMS

Other components of the FIRE software package include an advanced debugger (FIRE-SYMBUG), a text editor (FIRE-EDIT), an extended BASIC language interpreter (FIRE-BASIC), a macro-assembler (FIRE-MACRO) with relocatable loader (FIRE-RELOAD), an extended ANSII-77 FORTRAN IV compiler (FIRE-FORTRAN), a floppy-disk operating system (FIRE-FDOS), an interactive disk operating system (FIRE-IDOS) and the companion program libraries (FIRE-LIBE).

©IC MASTER 1979

FIRE COMPUTERS
To capitalize on the FIRE family's distinctive characteristics, a set of computer boards has been developed to meet a broad range of data-processing requirements for immediate application in users' systems:



- SPARK-16 for small, low-cost memory requirements
- BLAZE-16 with NOVA 3 capabilities for large, high-performance requirements.

Instruction execution times are given in *Table 1* for both the FIRE family and the NOVA computers.

SPARK-16 Microcomputer Board *(Figure 14)*
SPARK-16 is a double-sided 8" x 10" pc board designed as a vehicle for evaluating the 9440 MICROFLAME CPU. It may also be used as a stand-alone microcomputer for applications that require small amounts of memory. It includes the following:

- 16-bit 9440 MICROFLAME CPU
- 4K words of bipolar dynamic RAM (93481s)
- 2K words of autoload PROM (loaded with the FIREBUG Autoload program)
- Memory control with DMA capability
- Logic for a serial port — current loop (TTY) or RS232C interface
- 100-pin edge connector with the 9440 bus
- Connector for TTY/RS232C
- Control switches and display (Autoload, Continue, Halt, Reset).

SPARK-16 requires only a single 5 V, 4.5 A supply and a TTY or CRT terminal. When the Reset and Autoload switches are activated, FIREBUG provides a system ready to accept commands interactively from the terminal. Similar PROM resident programs, such as BABY BASIC, will be available as optional replacements for FIREBUG PROMs.

FOCVS XVI Computer Box

BLAZE-16 Minicomputer Board Set *(Figure 15)*
BLAZE-16 is a 16-bit microprogrammed minicomputer, implemented with the Macrologic bit-slice microprocessor set. It is compatible with the NOVA 3, as well as the 9440 MICROFLAME microprocessor, and executes the same instruction set. Implemented on two 15" x 15" pc boards, BLAZE-16 includes the subsystems listed on page 13.

Board 1 — BLAZE-16/C

- Macrologic microprogrammed CPU
- Memory control logic
- A 16K word memory array (using 93481 4K x 1 RAMs)
- Memory parity logic
- Memory mapping logic (up to 256K words addressing)
- Autoload logic and FIREBUG PROMs
- Input/Output bus converter

Board 2 — BLAZE-16/M

- A 16K word memory array (using 93481 4K x 1 RAMs)
- TTY/RS232C interface logic
- High-speed paper tape reader/punch interface logic
- Real-time clock.

The BLAZE-16 CPU can essentially be divided into two major parts — a 16-bit-wide data path and a microprogram control. The data path consists of four 9405A arithmetic logic register stacks, each with eight registers/accumulators, and four 9404 data path switches. A 9408 I^3L microprogram sequencer controls the 1024-word by 48-bit microprogram, which resides in twelve 1024 x 4 ROMs. In addition to the basic FIRE instruction set, the BLAZE-16 microprogram handles the multiply and divide instructions and the stack handling operations. It includes a self-test routine and 15 operator-console routines. About 70% of the microprogram memory is free for user microprogramming and future instruction-set expansion. BLAZE-16 operates in a pipeline mode with a 200 ns microcycle. A 16-bit-wide bidirectional bus, common to all peripheral devices as is that of the 9440-based system, transfers both addresses and data between the CPU and main memory. The memory arrays are designed to accommodate the 93483 16K x 1 bipolar RAMs, which expands BLAZE-16 to a 128K-word minicomputer system.

FOCVS XVI AND THERMOSTAT
The FOCVS XVI computer box features a 9-slot chassis, regulated power supply and a front-panel computer console. It is attractively designed for stand-alone use or to fit into a standard RETMA rack on chassis slides. The front panel console latches and displays the data and address; it has control switches for examining the memory and accumulator contents, for depositing data and for setting hardware breakpoints. Lights and control switches are also provided for examining and debugging the microprogram when FOCVS is used with BLAZE-16. The chassis accommodates up-to-nine standard 15" x 15" pc boards including BLAZE-16, and the NOVA-compatible controller and interface boards. The THERMOSTAT is a hand-held console designed for use in MICROFLAME-based systems without front-panel console control. □

THE HM-6100 MICROPROCESSOR

GENERAL DESCRIPTION

The HM-6100 is a single address, fixed 12-bit word length microprocessor that emulates the software operation of Digital Equipment Corporation's PDP-8/E. It is a monolithic circuit which is constructed using the Harris self-aligned, silicon-gate CMOS process. Operation is completely static from DC to 8MHz using a single supply (4-11V) with very low power consumption. The HM-6100 has a basic addressing capacity of 4096 12-bit words, but with optional hardware it can be extended to 32K. It performs a 12-bit ADD instruction in 2.5μ sec using a + 10V supply and in 5μsec using a 5V supply. An on-chip oscillator requires only an external crystal for operation, thereby eliminating the need for an external clock generator. All inputs and outputs permit simple interfaces to all TTL logic families. The HM-6100 is available in industrial or military temperature grades as well as Hi-Rel MIL-STD-883, Class B screened devices.

UNIQUE FEATURES

Unlike most other microprocessors which use multiple-byte instructions, the HM-6100 uses single-word instructions, affecting higher thru-put and shortening program size. Its system organization includes 128 directly addressable global registers located in the first page of RAM memory. As many as 25 register operations including register-register move and operate commands allow simple implementation of stack pointers, interrupt vectors, auto-indexing, etc. These features and more are summarized below:

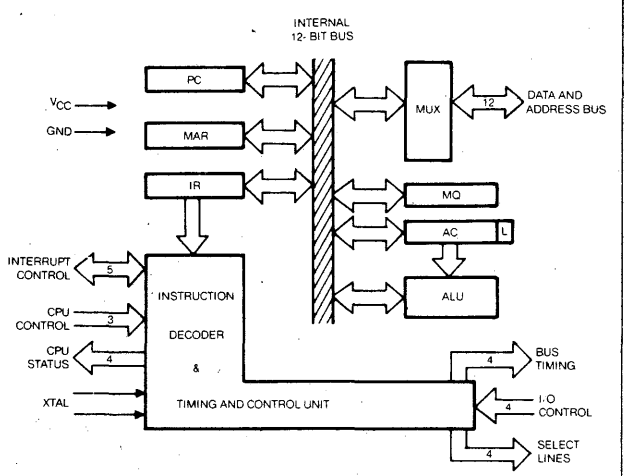
SINGLE-WORD INSTRUCTIONS
Memory referenced instructions combine both operation code and operand address in a single 12-bit word. This eliminates "immediate" instructions which minimizes program size and speeds execution.

RELOCATABLE MEMORY ORGANIZATION
Memory space is divided into blocks of 4096 words which are subdivided into 32 pages of 128 words each. Any memory reference instruction within a particular page specifies an operand address that is relative to the starting location of that page. Pages can be simply relocated by specifying a new starting address.

GLOBAL REGISTERS
The first 128 words of memory (page 0) are considered to be global registers since they are directly accessible from any memory location within the 4K address field.

AUTO-INDEXED REGISTERS
Memory locations 10_8-17_8 function as general purpose auto-indexed registers if they are used to store an indirect address. When the CPU fetches this address, the contents of the register will be incremented and maintained. This feature is particularly useful in memory search routines, data movement, data counters and pointers.

SINGLE-WORD I/O TRANSFER
A single instruction provides both I/O device address and control to an input-output device. The instruction format allows 9 bits to be user defined to accommodate a number of I/O configurations.



CONTROL PANEL FOR SYSTEM DEBUG
The HM-6100 can support a dedicated control panel memory. This feature is very useful in system debugging as it allows direct access to control panel monitor programs. Access is obtained on an interrupt basis by asserting the control panel request line ($\overline{\text{CPREQ}}$). In this way, control panel memory may occupy the same addressing space as the user program, yet be "transparent". The control panel request input is a true non-maskable interrupt and will be acknowledged even if the CPU is in the halt state.

©IC MASTER 1979

ARCHITECTURE

The HM-6100 architecture as shown in Figure 3 has three programmable 12-bit registers, an arithmetic logic unit (ALU) and associated timing and control circuitry to provide bus control, CPU control, DMA access and interrupt control.

Figure 3 HM-6100 ARCHITECTURE

INTERNAL DESCRIPTION

ACCUMULATOR/LINK (AC/L)

The AC is a programmable 12-bit register with which arithmetic and logical operations are performed. It is the source of destination for all programmed data transfers. The LINK is a 1-bit flip-flop that serves as a high-order extension of the AC.

MQ REGISTER (MQ)

The MQ is a programmable 12-bit temporary register. The contents of the AC may be transferred to the MQ. The MQ can be OR'ed with the AC and the result stored in the AC. The contents of the AC and MQ may also be exchanged.

PROGRAM COUNTER (PC)

The PC is a programmable 12-bit register which contains the address of the memory location from which the next instruction is fetched. Being 12-bits wide, the PC defines an address space of 4096 memory words. However, the PC can be effectively extended to address up to 32K memory words by using the HD-6102 MEDIC chip. The PC can be programmed from an external device to provide vectored interrupts.

MEMORY ADDRESS REGISTER (MAR)

The MAR is a 12-bit register which contains the address of the memory location that is currently being accessed. It is also used to control data transfers to and from memory and peripherals.

ALU

The ALU performs both arithmetic and logical operations such as 2's complement binary ADD, AND, OR and Complement. It can shift left or right, rotate or swap bytes. The AC always provides one input to the ALU while the second input is any one of the other registers.

INSTRUCTION REGISTER (IR)

The 12-bit IR contains the instruction that is to be executed by the CPU. The IR outputs to the Timing and Control Unit for instruction decoding.

MULTIPLEXER

The 12-bit bidirectional multiplexer handles data, address and instruction transfers on the DX bus on a time multiplexed basis.

TIMING AND CONTROL UNIT

This unit contains all ALU and register transfer logic as well as instruction decode circuitry and all memory and external device control logic. It also provides external timing and control signals to simplify CPU communication with peripherals, memory and control panel.

EXTERNAL INTERFACE

DATA AND ADDRESS BUS (DX) (12)

Bidirectional multiplexed bus used to communicate with external memory and I/O devices.

BUS TIMING (4)

Used by external logic to decode various time-multiplexed events such as read/write operations and external addresses from the DX bus.

SELECT LINES (4)

Used in conjunction with Bus Timing signals to enable main memory, control panel memory, or I/O devices.

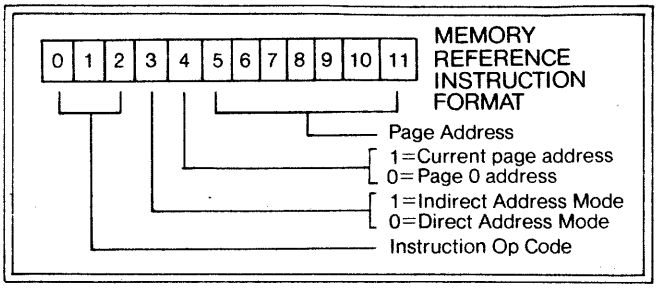
CPU CONTROL (3)

Used to Reset, Halt or single-step the CPU. Additionally, the $\overline{\text{WAIT}}$ input allows slow memory or I/O devices to be synchronized to the CPU. The $\overline{\text{WAIT}}$ input can be used to effectively power strobe the CPU.

INTERRUPT CONTROL (5)

Used to interrupt normal CPU operation for servicing control panel memory, I/O devices, or high speed data transfers between external devices (Direct Memory Access interrupt).

CPU STATUS (4)



These signals specify the following: 1) Direct/Indirect addressing mode; 2) Fetch/Execute status of machine cycle; 3) Link status; 4) Run/Halt CPU status.

I/O CONTROL (4)

Used to control data transfers between the PC or AC and external Input-Output devices.

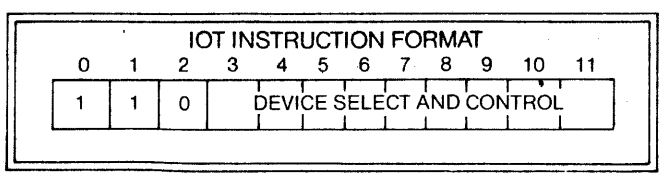
MEMORY ADDRESSING MODES

The HM-6100 uses a single 12-bit word for fast execution times, precision, and optimum software efficiency. All memory referenced instructions have the following object code format:

DIRECT ADDRESSING

The seven address bits (5-11) specify one word from a 128 word page. The memory page bit (4) specifies that word to be either in Page 0 (0$_8$ to 177$_8$) or within the current page of the instruction being executed. This allows global access to 128 general purpose memory locations in Page 0 (bit 4 = 0), in addition to 128 words within the current page (bit 4 = 1). This single instruction scheme requires no software overhead which is sometimes required in other processors utilizing 2- and 3-byte instructions.

INDIRECT ADDRESSING



Standard indirect addressing is offered. The CPU simply interprets the contents of the memory location that is pointed to by the page address as the effective address. A memory reference instruction can access an indirect memory address either on page 0 or on the current page.

AUTO-INDEXED, INDIRECT ADDRESSING

When RAM locations 10$_8$ to 17$_8$ on page 0 are indirectly addressed, their contents are auto-incremented and returned. This simplifies sequential memory accessing. Data tables can be read sequentially by addressing the table through any one of these locations. Similarly, data movement is made easy by executing an indirect read and then an indirect write through any two of these locations.

INPUT-OUTPUT TRANSFER INSTRUCTION (IOT) FORMAT

All I/O transfer instructions have single-word formats with an octal OPCODE of six as shown below. The remaining nine bits (3-11) are user defined to provide device selection and control.

The only codes which cannot be used for I/O transfers are 6000$_8$ to 6007$_8$. They are reserved for internal processor interrupt control.

Three types of I/O transfers may be used: 1) *Programmed Data Transfers* provide a means of communicating with relatively slow peripherals such as teletypes, cassettes, card readers, CRT displays, etc. 2) *Interrupt Transfers* use the interrupt system with external hardware to service several peripherals on a vectored priority basis. 3) *Direct Memory Access (DMA) Transfers* provide a means for transferring high speed data between memory and peripherals under external control.

For typical IOT instructions refer to the HM-6100 Instruction Set Summary.

HM-6100 CPU PINS AND SIGNALS

The CPU pins and signals are illustrated in Figure 4. The 12-bit bidirectional bus is shown as DX0- DX11 with DXO being the most-significant bit. Each pin is briefly described in Table 1 below:

Figure 4

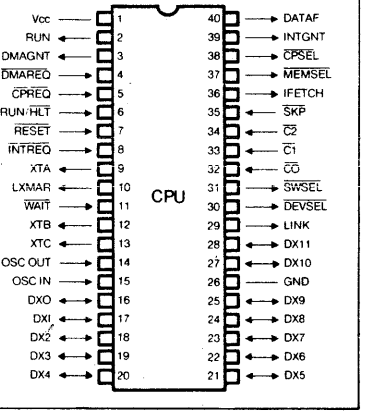


TABLE 1. PIN FUNCTION LIST

PIN NAME	DESCRIPTION	FUNCTION
DX0-DX11	Multiplexed Data and Address Bus	Data and Address Bus
XTA, XTB, XTC	External timing output signals for decoding bus operations	Bus Timing
LXMAR	Output for latching an address into an external device	
$\overline{DEVSEL}$	I/O device select output	Select Lines
$\overline{SWSEL}$	Read select for an input device	
$\overline{MEMSEL}$	Memory select output	
$\overline{CPSEL}$	Control Panel memory select output	
RUN/$\overline{HLT}$	CPU Run/Halt input	CPU Control
$\overline{RESET}$	CPU Reset input	
$\overline{WAIT}$	CPU input to synchronize slow external devices on the bus	
$\overline{DMAREQ}$	DMA request input	Interrupt Control
DMAGNT	DMA grant output, bus is floated	
$\overline{INTREQ}$	I/O interrupt request input	
INTGNT	Interrupt grant output	
$\overline{CPREQ}$	Interrupt request for Control Panel memory access	
IFETCH	Signifies an instruction fetch cycle	CPU Status
DATAF	Signifies the execute phase for indirect addressing	
LINK	Accumulator extension bit	
RUN	CPU Run/Halt status	
$\overline{C0}$ $\overline{C1}$ $\overline{C2}$ $\overline{SKP}$	Externally controlled inputs which define transfer operations between I/O devices, and the AC or PC	I/O Control
OSC OUT	Crystal or external clock input	Power and Clock
OSC IN	Crystal or external clock input	
VCC, GND	Power supply inputs

HM-6100 SPECIFICATIONS

Harris thoroughly tests all of its microprocessor products at various operating frequencies and supply voltages. The HM-6100 parameters shown below are specified at room temperature, TA = +25°C, only. For complete specifications over the military and industrial temperature ranges contact your nearest Harris representative for data sheets.

DC CHARACTERISTICS (TA=+25°C)

			HM-6100A VCC=+10V		HM-6100 VCC=+5V		HM-6100C VCC=+5V		
PARAMETER	SYMBOL	CONDITIONS	MIN	MAX	MIN	MAX	MIN	MAX	UNITS
Input Voltage Logical "1" Logical "0"	 VIH VIL		 70%VCC	 20%VCC	 70%VCC	 20%VCC	 70%VCC	 0.8	 V V

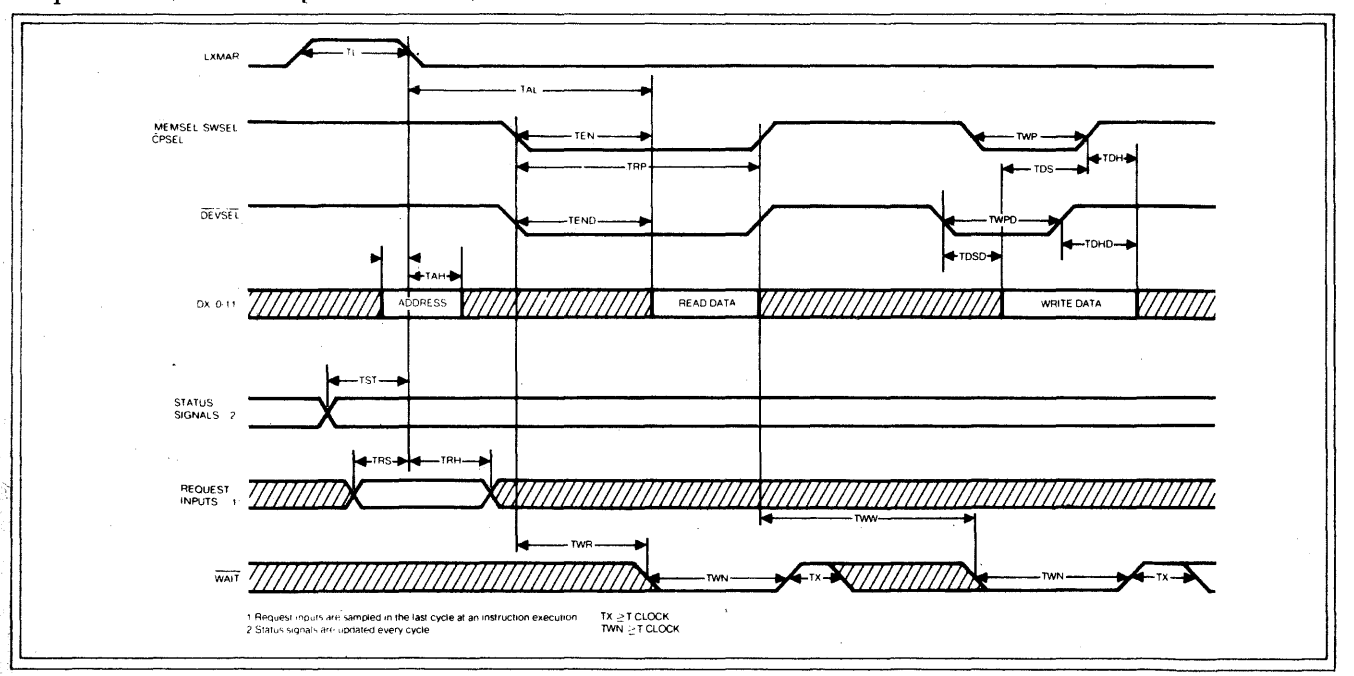
Input-Output	17	4.25	8.50	10.20

For a complete listing of the instruction set see Instruction Set Summary.

©IC MASTER 1979



STATIC TIMING

The following illustrates the timing of the CPU when its operating frequency is low enough that propagation delays can be ignored. It effectively shows the timing of the CPU when it is single-clocked.

DYNAMIC TIMING

The dynamic or high frequency timing illustrates the propagation delays at specified operating frequencies. (Refer to specifications.) It defines the interface requirements for memory and I/O devices on the bus.

PRODUCT OVERVIEW

MINIMUM SYSTEM

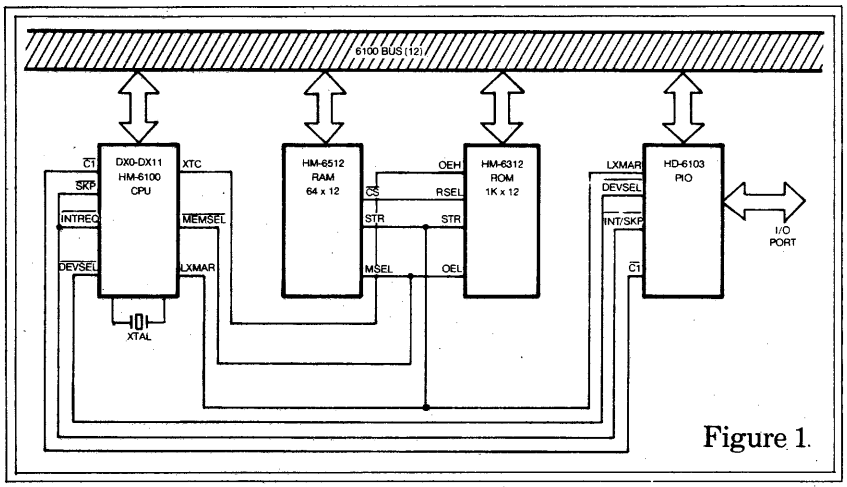

Figure 1.

4K RAM SYSTEM

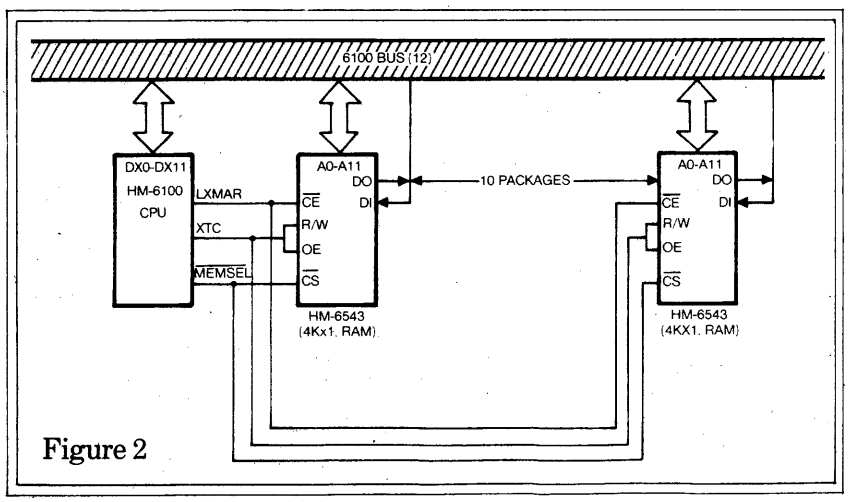

Figure 2

The Harris 12-bit CMOS microcomputer components have been optimized for low operating power, wide operating voltage range, high operating speed and direct compatibility with the HM-6100 microprocessor bus. For example, the minimum system shown in Figure 1 consists of only four packages, yet offers 64 X 12 random access memory (RAM), 1024 X 12 read only memory (ROM) and a 20-bit parallel I/O port. Using higher density CMOS memories, a complete 4K RAM system can be built with only twelve HM-6543s as shown in Figure 2. For larger system capability, the HD-6102 extends the address field of the HM-6100 CPU to 32K. Harris also offers a complete line of high speed CMOS Bus Drivers for increasing system drive capability as well as a diversified line of CMOS communications products. These and other CMOS microcomputer products are summarized below.

MINIMUM CMOS SYSTEM

SUPPORT SYSTEMS

Harris supports its microprocessor-based systems through an extensive variety of proven PDP-8 software and development systems. The latest PDP-8 development system, the DECstation 78, incorporates LSI technology to reduce size, weight and cost of first generation PDP-8s. It supports a number of peripherals including dual floppy disks, high speed printers, MODEMs, etc.

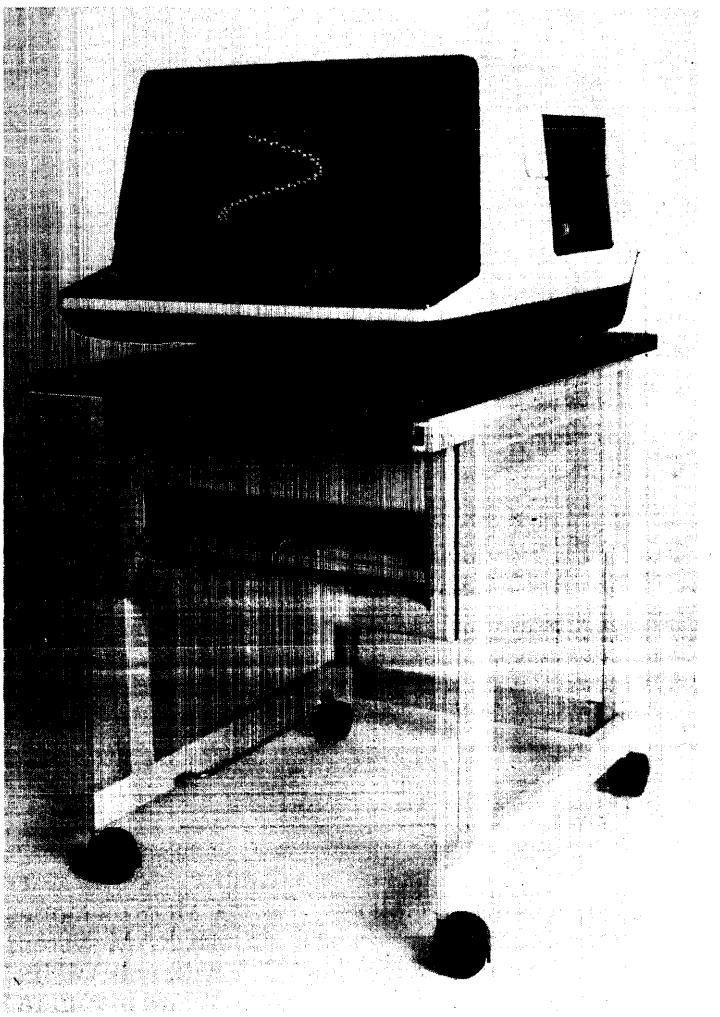
For machine language programming and prototyping of the HM-6100 system, Harris offers an inexpensive fully assembled, single board microcomputer with interactive keyboard and display.

DECstation 78 DEVELOPMENT SYSTEM

The DECstation 78 is recommended for full software support and can be purchased from Harris with a service contract agreement from DEC. It is a fully integrated, compact, inexpensive minicomputer and display system that offers all the best features of the PDP-8 and more. Some of its features are:

OS/78 OPERATING SYSTEM
Supports a number of high-level programming languages such as BASIC and FORTRAN IV, and provides a comprehensive set of software tools and utility programs.

DISPLAY AND MINICOMPUTER SYSTEM
Consists of a single compact unit, housing both the 6100-based microcomputer and CRT terminal for maximum processing capability at minimum cost. (See photograph)



FLOPPY DISK UNIT
Includes two drives, a microprogrammed controller module and a READ/WRITE electronics module and is capable of storing 128,128 12-bit words per drive in industry standard format.

ASYNCHRONOUS COMMUNICATIONS INTERFACE
Two serial EIA RS-232C asynchronous interface ports are suitable for primary and secondary communications applications.

PARALLEL I/O PORT
Supports printers and custom interfaces and provides bidirectional 12-bit transfers at rates up to 15K words per second.

ELECTRONIC PROGRAM INJECTION PORT
Provides high-speed program loading under the control of a pre-programmed ROM unit—an inexpensive way of customizing the DECstation 78 for use in fixed function environments.

The DECstation 78 is a full capability minicomputer system designed for easy user installation. It requires no special wiring or electronic expertise to assemble.

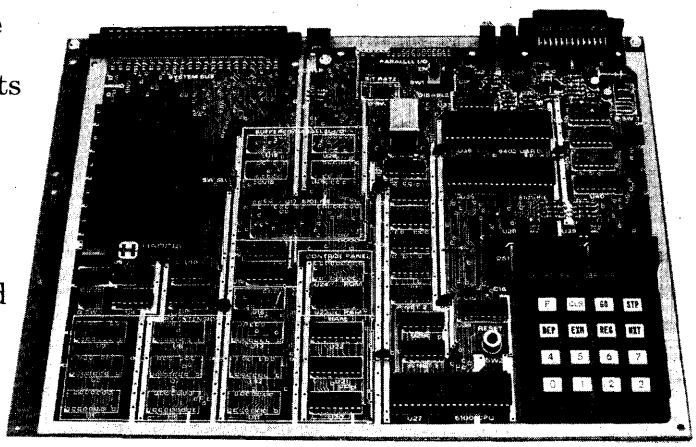
MICRO-12 CMOS MICROCOMPUTER SYSTEM

The Harris MICRO-12 (HB-61000) is a fully assembled and tested all CMOS single board 12-bit microcomputer. (See photograph) It consists of the following:

- ☐ ROM Monitor (1K x 12)
- ☐ 256 Word RAM Memory—expandable to 1K
- ☐ Allocated breadboard space
- ☐ 16-key Keyboard
- ☐ 8-digit LED Display
- ☐ TTY/Cassette Interface
- ☐ RS-232 Interface

The ROM Monitor program uses a 1024 X 12 CMOS ROM (HM-6312) for system monitoring and display control. It does not occupy any of the user RAM memory space, since it resides in control panel memory. The ROM Monitor supports the following commands:



MONITOR COMMANDS

- ☐ **Examine**—Displays the contents of a selected memory location
- ☐ **Deposit**—Alters the contents of a selected memory location
- ☐ **Register-Examine**—Displays PC, AC, MQ and Link
- ☐ **Next**—Increments PC
- ☐ **Execute**—Starts user program
- ☐ **Single Cycle**—Executes a single instruction
- ☐ **Clear**—Clears AC, MQ and Link and sets PC to 7777_8
- ☐ **Function**—Sets keyboard for function commands

FUNCTION COMMANDS

- ☐ **Binary Load**—Loads user program in binary format from TTY or Tape Cassette
- ☐ **Binary Punch**—Outputs user program in binary format to TTY or Tape Cassette
- ☐ **Octal Listing**—Prints user program to TTY
- ☐ **Breakpoint Set**—Sets four independent breakpoints

The MICRO-12 is supplied complete with a documentation package consisting of details on using the system, theory of operation, circuit diagrams and a listing of the ROM Monitor program.

SUPPORT SOFTWARE

PAL 8 (ABSOLUTE ASSEMBLER)
An 8K, two pass assembler designed to run under the OS/78 operating systems. It accepts source files in PAL language and generates absolute binary files.

MACREL (RELOCATABLE ASSEMBLER)
A macro-assembler that produces relocatable program sections. Ideal for large system usage to reduce software development time.

FOPAL III (CROSS ASSEMBLER)
A cross assembler written in standard FORTRAN. It is functionally identical to the PDP-8/E PAL III Assembler, supplied with the Extended Software Package. Call factory for more information.

DECUS (DIGITAL EQUIPMENT COMPUTER USERS SOCIETY)
Provides a vehicle through which HM-6100 users can exchange ideas and information. This organization makes readily available an extensive library of proven user programs which in many cases can reduce your development efforts.

HD-4702/6405

CMOS PROGRAMMABLE BIT RATE GENERATOR

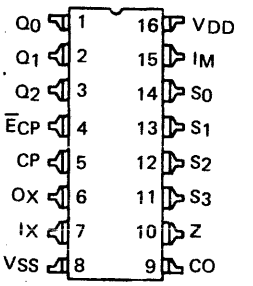
Features

- HD-4702 – PROVIDES 13 COMMONLY USED BIT RATES
- HD-6405 – PROVIDES 15 COMMONLY USED BIT RATES
- USES A 2.4576MHz CRYSTAL/INPUT FOR STANDARD FREQUENCY OUTPUT (16 TIMES BIT RATE)
- TTL COMPATIBLE – OUTPUT WILL SINK 1.6mA
- LOW POWER DISSIPATION HD-6405 4.0mW TYP. @ 2.4576MHz
  HD-4702 4.5mW TYP. @ 2.4576MHz
- CONFORMS TO EIA RS-404
- ONE HD-4702 OR HD-6405 CONTROLS UP TO EIGHT TRANSMISSION CHANNELS
- INITIALIZATION CIRCUIT FACILITATES DIAGNOSTIC FAULT ISOLATION
- ON-CHIP INPUT PULL-UP CIRCUIT – HD-4702 ONLY

Description

The HD-4702/6405 Bit Rate Generator provides the necessary clock signals for digital data transmission systems, such as UART. It generates 13(HD-4702) or 15(HD-6405) commonly used bit rates using an on-chip crystal oscillator or an external input. For conventional operation generating 16 output clock pulses per bit period, the input clock frequency must be 2.4576MHz (i.e. 9600 Baud x 16 x 16, since there is an internal ÷16 prescaler). A lower input frequency will result in a proportionally lower output frequency.

The HD-4702/6405 can provide multi-channel operation with a minimum of external logic by having the clock frequency CO and the ÷8 prescaler outputs Q_0, Q_1, Q_2 available externally. All signals have a 50% duty cycle except 1800 Baud and 2000 Baud which has less than 0.39% distortion and 3600 Baud which has less than 0.78% distortion.



The four rate select inputs (S_0-S_3) select which bit rate is at the output (Z). The table lists select code and output bit rate. Two of the 16 for the HD-4702 and one of the 16 for the HD-6405 do not select an internally generated frequency, but select an input into which the user can feed either a different frequency, or a static level (High or Low) to generate "ZERO BAUD".

The bit rate most commonly used in modern data terminals (110, 150, 300, 1200, 2400 Baud) require that no more than one input be grounded for the HD-4702, which is easily achieved with a single, 5-position switch.

The HD-4702/6405 has an initialization circuit which generates a common master reset for all flip-flops. This signal is derived from a digital differentiator that senses the first high level on the CP input after the $\overline{E}_{CP}$ input goes low. When $\overline{E}_{CP}$ is high, selecting the crystal input, CP must be low. A high level on CP would apply a continuous reset.

For the HD-4702, all inputs except I_X have on-chip pull-up circuits which provide TTL compatibility and eliminate the need to tie a permanently high input to V_{DD}.

Pinout

PIN NAMES

$\overline{CP}$	External Clock Input
$\overline{E}_{CP}$	External Clock Enable Input (Active Low)
I_X	Crystal Input
IM	Multiplexed Input
S_0 - S_3	Rate Select Inputs
CO	Clock Output
OX	Crystal Drive Output
Q_0 - Q_2	Scan Counter Outputs
Z	Bit Rate Output

Truth Tables

	t_{PLH} t_{PHL}	Propagation Delay, CO to Q_n			⑤			⑤	ns ns	
	t_{PLH} t_{PHL}	Propagation Delay, CO to Z			45 40			45 40	ns ns	
	t_{TLH} t_{THL}	Output Transition Time (except OX)			80 40			80 40	ns ns	
	t_s t_h	Set-Up Time, Select to CO Hold Time, Select to CO	175 0			175 0			ns ns	$C_L \leq$ 7pF on OX
	t_s t_h	Set-Up Time, IM to CO Hold Time, IM to CO	175 20			175 20			ns ns	C_L = 15pF Input Transition Times ≤ 20ns
	$t_{WCP(L)}$ $t_{WCP(H)}$	Minimum Clock Pulse-Width Low and High	60 60			60 60			ns ns	
	$t_{WCP(L)}$ $t_{WCP(H)}$	Minimum IX Pulse Width, Low and High	80 80			80 80			ns ns	

1. Input Current and Quiescent Power Supply Current are relatively higher for this device because of active pull-up circuits on all inputs except IX. This is done for TTL compatibility.
2. Propagation Delays (t_{PLH} and t_{PHL}) and Output Transistion Times (t_{TLH} and t_{THL}) will change with Output Load Capacitance (C_L). Set-Up Times (t_s), Hold Times (t_h), and Mininum Pulse Widths (t_w) do not vary with load capacitance.
3. The first High Level Clock Pulse after $\overline{E}_{CP}$ goes Low and must be at least 350ns long to guarantee reset of all Counters.
4. It is recommended that input rise and fall times to the Clock Inputs (CP, IX) be less than 15ns.
5. For multichannel operation, Propagation Delay (CO to Q_n) plus Set-Up Time, Select to CO, is guaranteed to be ≤ 190ns.

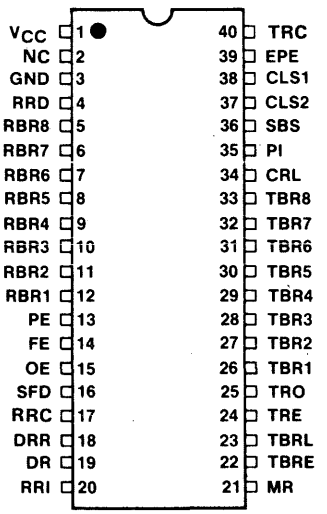
HD-6402

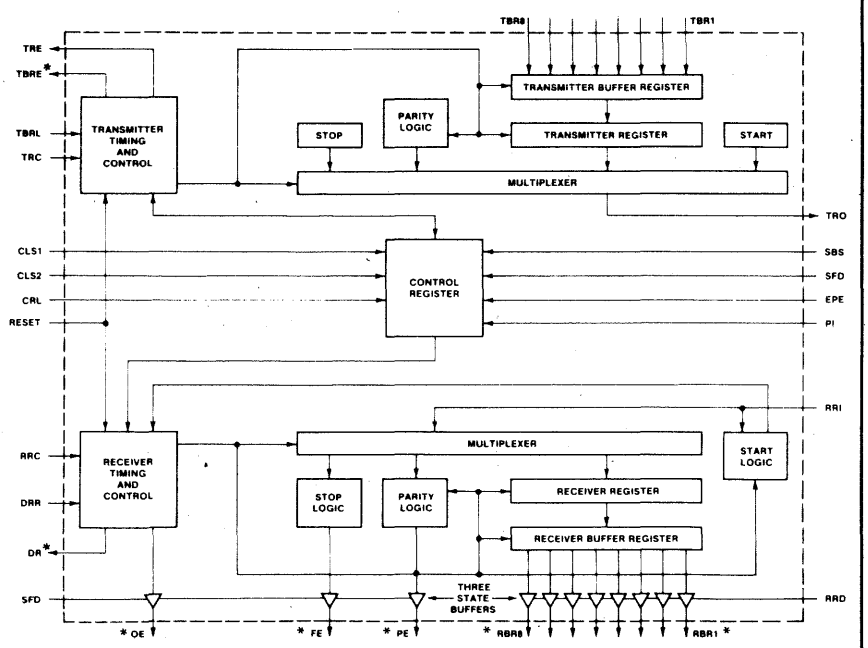
CMOS/LSI Universal Asynchronous Receiver Transmitter (UART)

Features



- OPERATION FROM D.C. TO 4.0MHz @10.0 VOLTS
- LOW POWER-TYR. 10mW @ 2.0MHz AND 5.0 VOLTS
- 4 TO 11 VOLT OPERATION
- PROGRAMMABLE WORD LENGTH, STOP BITS AND PARITY
- AUTOMATIC DATA FORMATTING AND STATUS GENERATION
- COMPATIBLE WITH INDUSTRY STANDARD UART'S
- SINGLE POWER SUPPLY

Description



The HD-6402 is a CMOS/LSI subsystem for interfacing computers or microprocessors to an asynchronous serial data channel. The receiver converts serial start, data, parity and stop bits to parallel data verifying proper code transmission, parity, and stop bits. The transmitter converts parallel data into serial form and automatically adds start, parity, and stop bits. The data word length can be 5, 6, 7 or 8 bits. Parity may be odd or even. Parity checking and generation can be inhibited. The stop bits may be one or two or one and one-half when transmitting 5 bit code.

The HD-6402 can be used in a wide range of applications including modems, printers, peripherals and remote data aquisition systems. CMOS/LSI technology permits operation clock frequencies up to 4.0MHz (250K Baud) an improvement of 10 to 1 over previous PMOS UART designs. Power requirements, by comparison, are reduced from 300mW to 10mW. Status logic increases flexibility and simplifies the user interface.

Transmitter Operation

The transmitter section accepts parallel data, formats it and transmits it in serial form on the TROutput terminal. Ⓐ Data is loaded into the transmitter buffer register from the inputs TR1 through TR8 by a logic low on the TBRLoad input. Valid data must be present at least t_{SET} prior to and t_{HOLD} following the rising edge of TBRL. If words less than 8 bits are used, only the least significant bits are used. The character is right justified into the least significant bit, TR1. Ⓑ The rising edge of TBRL clears TBREmpty. 0 to 1 clock cycles later, data is transferred to the transmitter register; TREmpty is cleared; TBR-Empty is set high; and serial data transmission is started. Output data is clocked by TRClock. The clock rate is 16 times the data rate. Ⓒ A second pulse on TBRLoad loads data into the transmitter buffer register. Data transfer to the transmitter register is delayed until transmission of the current character is complete. Ⓓ Data is automatically transferred to the transmitter register and transmission of that character begins one clock cycle later.

NOTE 1: All devices guaranteed at worst case limits. Room temperature, 5V data provided for information-not guaranteed.

Receiver Operation

Data is received in serial form at the RInput. When no data is being received, RInput must remain high. The data is clocked through the RRClock. The clock rate is 16 times the data rate. Ⓐ A low level on DRReset clears the DReady line. Ⓑ During the first stop bit data is transferred from the receiver register to the RBRegister. If the word is less than 8 bits, the unused most significant bits will be a logic low. The output character is right justified to the least significant bit RBR1. A logic high on OError indicates overruns. An overrun occurs when DReady has not been cleared before the present character was transferred to the RBRegister. Ⓒ ½ clock cycle later DReady is reset to a logic high, PError and FError are evaluated. A logic high on FError indicates an invalid stop bit was received, a framing error. A logic high on PError indicates a parity error.

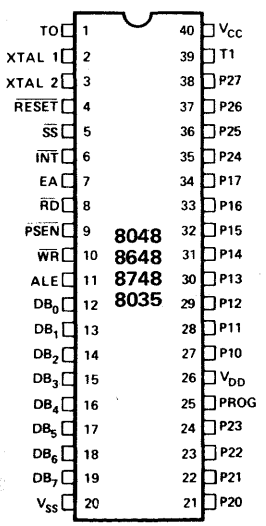
Notice: This is not a final specification. Some parametric limits are subject to change.

8048/8648/8748/8035

SINGLE COMPONENT 8-BIT MICROCOMPUTER

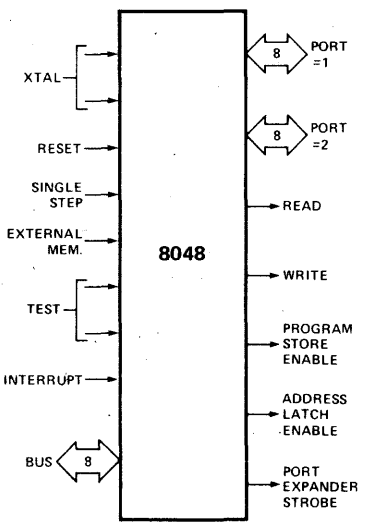
- 8048 Mask Programmable ROM
- 8648 One-Time Factory Programmable EPROM
- 8748 User Programmable/Erasable EPROM
- 8035 External ROM or EPROM

- 8-Bit CPU, ROM, RAM, I/O in Single Package
- Interchangeable ROM and EPROM Versions
- Single 5V Supply
- 2.5 μsec and 5.0 μsec Cycle Versions: All Instructions 1 or 2 Cycles
- Over 90 Instructions: 70% Single Byte
- 1K x 8 ROM/EPROM
  64 x 8 RAM
  27 I/O Lines
- Interval Timer/Event Counter
- Easily Expandable Memory and I/O
- Compatible with 8000 Series Peripherals
- Single Level Interrupt



The Intel® 8048/8648/8748/8035 is a totally self-sufficient 8-bit parallel computer fabricated on a single silicon chip using Intel's N-channel silicon gate MOS process.

The 8048 contains a 1K x 8 program memory, a 64 x 8 RAM data memory, 27 I/O lines, and an 8-bit timer/counter in addition to onboard oscillator and clock circuits. For systems that require extra capability, the 8048 can be expanded using standard memories and MCS-80™ (8080A) peripherals. The 8035 is the equivalent of an 8048 without program memory. The 8035L has the RAM power down mode of the 8048 while the 8035 does not.



To reduce development problems to a minimum and provide maximum flexibility, three interchangeable pin-compatible versions of this single component microcomputer exist: the 8748 with user-programmable and erasable EPROM program memory for prototype and preproduction systems, the 8048 with factory-programmed mask ROM program memory for low cost, high volume production, and the 8035 without program memory for use with external program memories.

This microprocessor is designed to be an efficient controller as well as an arithmetic processor. The 8048 has extensive bit handling capability as well as facilities for both binary and BCD arithmetic. Efficient use of program memory results from an instruction set consisting mostly of single byte instructions and no instructions over 2 bytes in length.

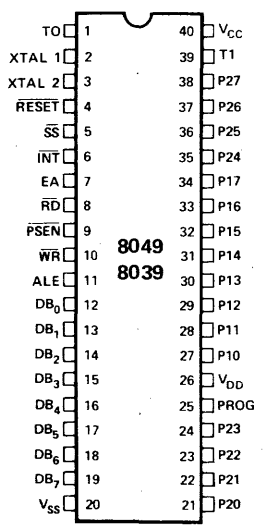
NEW HIGH PERFORMANCE 8049/8039/8039-6 SINGLE COMPONENT 8-BIT MICROCOMPUTER

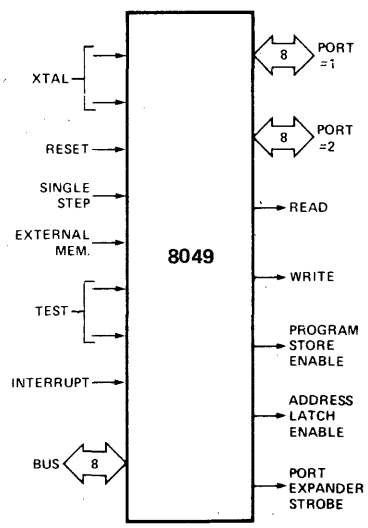
*8049 Mask Programmable ROM
*8039 External ROM or EPROM
*New 11 MHz Operation

- 8-Bit CPU, ROM, RAM, I/O in Single Package
- Single 5V ± 10% Supply
- 1.36 μsec Cycle; All Instructions 1 or 2 Cycles
- Over 90 Instructions: 70% Single Byte
- Pin Compatible with 8048/8748
- 2K x 8 ROM
  128 x 8 RAM
  27 I/O Lines
- Interval Timer/Event Counter
- Easily Expandable Memory and I/O
- Compatible with MCS Memory and I/O
- Single Level Interrupt



The Intel® 8049/8039/8039-6 is a totally self-sufficient 8-bit parallel computer fabricated on a single silicon chip using Intel's N-channel silicon gate MOS process.

The 8049 contains a 2K x 8 program memory, a 128 x 8 RAM data memory, 27 I/O lines, and an 8-bit timer/counter in addition to on board oscillator and clock circuits. For systems that require extra capability, the 8049 can be expanded using standard memories and MCS-80™/MCS-85™ peripherals. The 8039 is the equivalent to an 8049 without program memory. The 8039-6 is a lower speed (6MHz) version of the 8039.



To reduce development problems to a minimum and provide maximum flexibility, two interchangeable pin-compatible versions of this single component microcomputer exist: the 8049 with factory-programmed mask ROM program memory for low-cost high volume production, and the 8039 without program memory for use with external program memories in prototype and preproduction systems.

This microprocessor is designed to be an efficient controller as well as an arithmetic processor. The 8049 has extensive bit handling capability as well as facilities for both binary and BCD arithmetic. Efficient use of program memory results from an instruction set consisting mostly of single byte instructions and no instructions over two bytes in length.

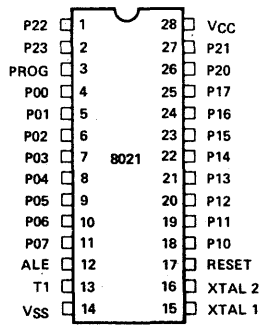
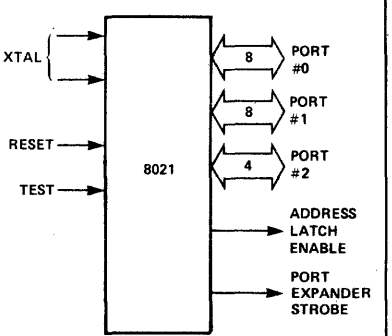
8021
SINGLE COMPONENT 8-BIT MICROCOMPUTER

- 8-Bit CPU, ROM, RAM, I/O in Single 28-Pin Package
- Single 5V Supply (+4.5V to 6.5V)
- 10 μsec Cycle; All Instructions 1 or 2 Cycles
- Instructions —8748 Subset
- High Current Drive Capability—2 Pins
- 1K × 8 ROM
  64 × 8 RAM
  21 I/O Lines
- Interval Timer/Event Counter
- Clock Generated With Single Resistor or Inductor
- Zero-Cross Detection Capability
- Easily Expandable I/O



The Intel® 8021 is a totally self-sufficient 8-bit parallel computer fabricated on a single silicon chip using Intel's N-channel silicon gate MOS process. The features of the 8021 include a subset of the 8048 optimized for low cost, high volume applications, plus additional I/O flexibility and power.

The 8021 contains a 1K X 8 program memory, a 64 X 8 data memory, 21 I/O lines, and an 8-bit timer/event counter, in addition to on-board oscillator and clock circuits. For systems that require extra I/O capability, the 8021 can be expanded using the 8243 or discrete logic.



This microprocessor is designed to be an efficient controller as well as an arithmetic processor. The 8021 has bit handling capability as well as facilities for both binary and BCD arithmetic. Efficient use of program memory results from an instruction set consisting mostly of single byte instructions and no instructions over two bytes in length.

To minimize development problems and maximize flexibility, an 8021 system can be easily designed using the 8021 emulation board, EMB-21. The EMB-21 contains a 40-pin socket which can accommodate either the 8748 shipped with the board or an ICE-48 plug. Also, the necessary discrete logic to reproduce the 8021's additional I/O features is included.

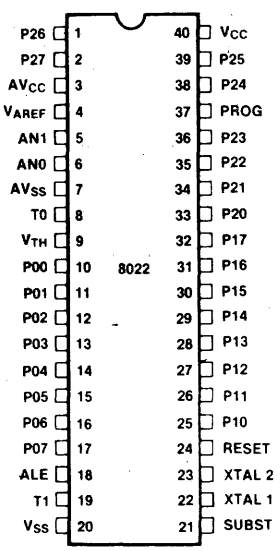
Notice: This is not a final specification. Some parametric limits are subject to change.

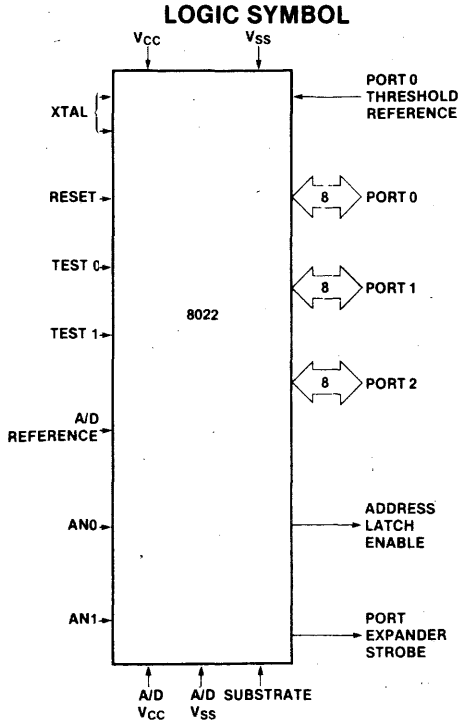
8022

SINGLE COMPONENT 8-BIT MICROCOMPUTER WITH ON-CHIP A/D CONVERTER



- 8-Bit CPU, ROM, RAM, I/O in Single 40-Pin Package
- On-Chip 8-Bit A/D Converter; Two Input Channels
- 8 Comparator Inputs (Port 0)
- Zero-Cross Detection Capability
- Single 5V Supply (4.5V to 6.5V)
- High Current Drive Capability — 2 Pins
- Two Interrupts — External and Timer
- 2K × 8 ROM, 64 × 8 RAM, 28 I/O Lines
- 10 μsec Cycle; All Instructions 1 or 2 Cycles
- Instructions — 8048 Subset
- Interval Timer/Event Counter
- Clock Generated with Single Resistor, Inductor, or Crystal
- Easily Expandable I/O

The Intel® 8022 is the newest member of the MCS-48™ family of single chip 8-bit microcomputers. It is designed to satisfy the requirements of low cost, high volume applications which involve analog signals, capacitive touchpanel keyboards, and/or large ROM space. The 8022 addresses these applications by integrating many new functions on-chip, such as A/D conversion, comparator inputs and zero-cross detection.



The features of the 8022 include 2K bytes of program memory (ROM), 64 bytes of data memory (RAM), 28 I/O lines, an on-chip 8-bit A/D converter with two input channels, an 8-bit port with comparator inputs for interfacing to low voltage capacitive touchpanels or other non-TTL interfaces, external and timer interrupts, and zero-cross detection capability. In addition, it contains the 8-bit interval timer/event counter, on-board oscillator and clock circuitry, single 5V power supply requirement, and easily expandable I/O structure common to all members of the MCS-48 family.

The 8022 is designed to be an efficient controller as well as an arithmetic processor. It has bit handling capability plus facilities for both binary and BCD arithmetic. Efficient use of program memory results from using the MCS-48 instruction set which consists mostly of single byte instructions and has extensive conditional jump and direct table lookup capability. Program memory usage is further reduced via the 8022's hardware implementation of the A/D converter which simplifies interfacing to analog signals.

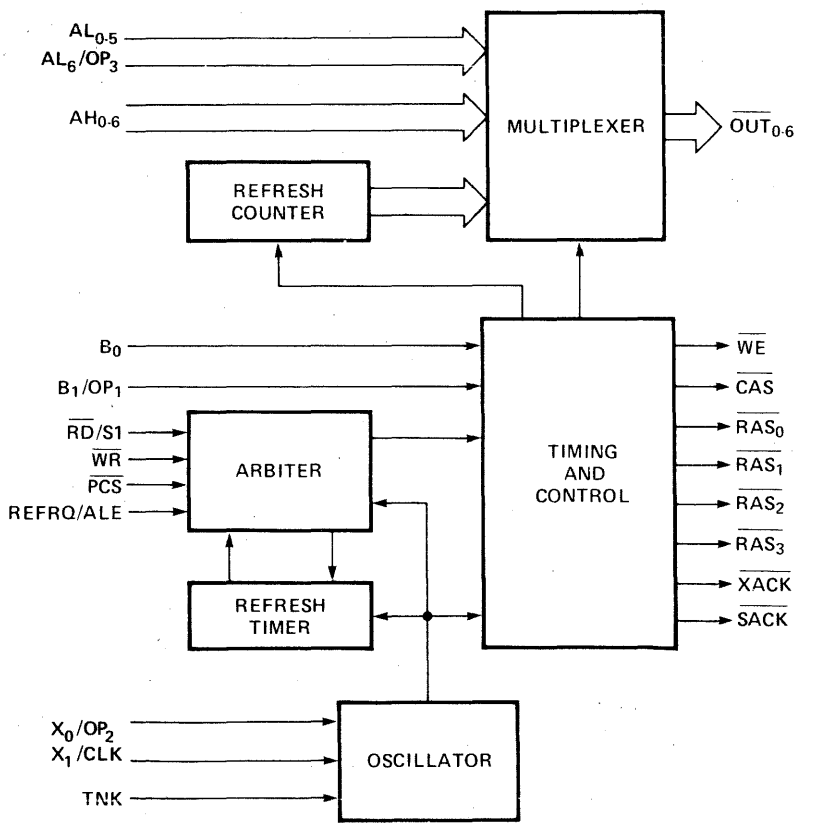
ADVANCE INFORMATION
Characteristics are subject to change without notice.

8202
DYNAMIC RAM CONTROLLER

- **Provides All Signals Necessary to Control 2104A, 2116, or 2117 Dynamic Memories**
- **Directly Addresses and Drives Up to 64K Bytes Without External Drivers**
- **Provides Address Multiplexing and Strobes**
- **Provides a Refresh Timer and a Refresh Counter**
- **Refresh Cycles May be Internally or Externally Requested**
- **Provides High Speed Refresh/Memory Access Request Arbitration**
- **Provides Transparent Refresh Capability**
- **Fully Compatible with Intel® 8080A and 8085A Microprocessors**
- **Decodes 8085A Status for Advanced Read Capability**
- **Provides System Acknowledge and Transfer Acknowledge Signals**
- **Internal or External Clock Capability**



The 8202 is a Dynamic RAM System Controller designed to provide all signals necessary to use 2104A, 2116, or 2117 Dynamic RAMs in microcomputer systems. The 8202 provides multiplexed addresses and address strobes, as well as refresh/access arbitration. Refresh cycles can be started internally or externally.

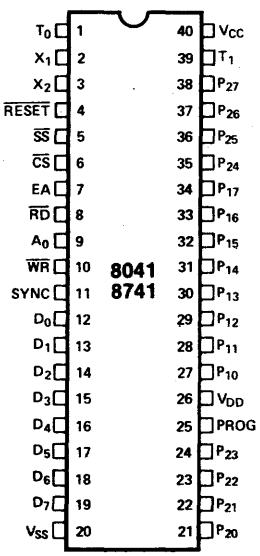
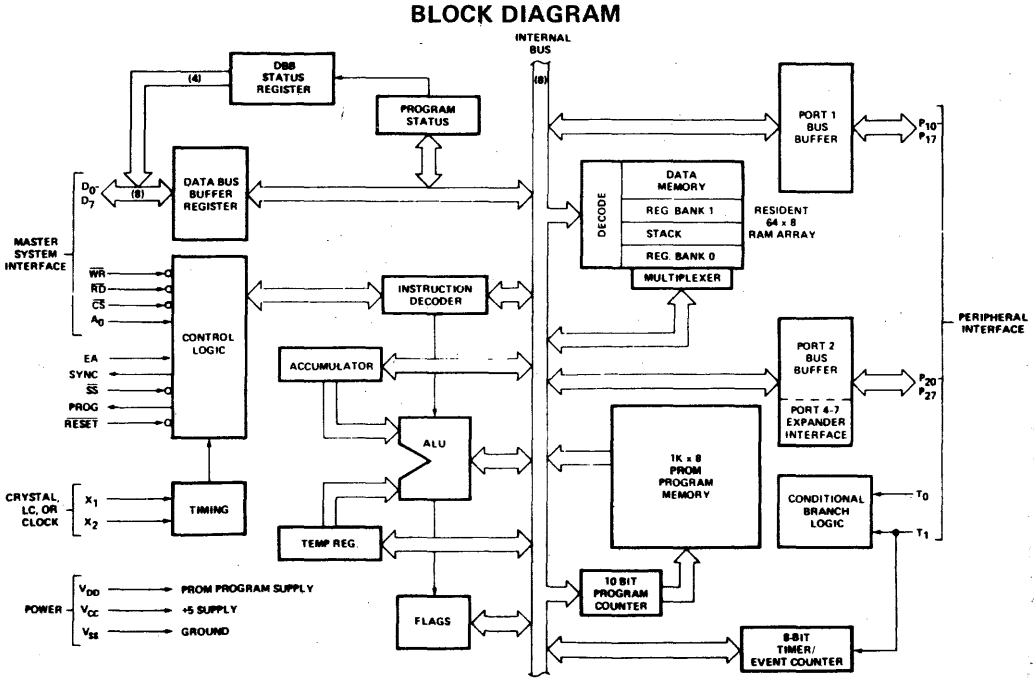
8041/8741
UNIVERSAL PERIPHERAL INTERFACE
8-BIT MICROCOMPUTER

- **Fully Compatibnle with MCS-80™, MCS-85™ and MCS-48™ Microprocessor Families**
- **Single Level Interrupt**
- **8-Bit CPU plus ROM, RAM, I/O, Timer and Clock in a Single Package**
- **Single 5V Supply**
- **Alternative to Custom LSI**
- **Pin Compatible ROM and EPROM Versions**
- **1K × 8 ROM/EPROM, 64 × 8 RAM, 18 Programmable I/O Pins**
- **Asynchronous Data Register for Interface to Master Processor**
- **Expandable I/O**



The Intel® 8041/8741 is a general purpose, programmable interface device designed for use with a variety of 8-bit microprocessor systems. It contains a low cost microcomputer with program memory, data memory, 8-bit CPU, I/O ports, timer/counter, and clock in a single 40-pin package. Interface registers are included to enable the UPI device to function as a peripheral controller in MCS-80™, MCS-85™, MCS-48™, and other 8-bit systems.

The UPI-41™ has 1K words of program memory and 64 words of data memory on-chip. To allow full user flexibility the program memory is available as ROM in the 8041 version or as UV-erasable EPROM in the 8741 version. The 8741 and the 8041 are fully pin compatible for easy transition from prototype to production level designs.



The device has two 8-bit, TTL compatible I/O ports and two test inputs. Individual port lines can function as either inputs or outputs under software control. I/O can be expanded with the 8243 device which is directly compatible and has 16 I/O lines. An 8-bit programmable timer/counter is included in the UPI device for generating timing sequences or counting external inputs. Additional UPI features include: single 5V supply, low power standby mode (in the 8041), single-step mode for debug (in the 8741), single level interrupt, and dual working register banks.

Because it's a complete microcomputer, the UPI provides more flexibility for the designer than conventional LSI interface devices. It is designed to be an efficient controller as well as an arithmetic processor. Applications include keyboard scanning, printer control, display multiplexing and similar functions which involve interfacing peripheral devices to microprocessor systems.

- **Up to 64K Baud Transfers**
- **Two User Programmable Modem Control Ports**
- **Automatic FCS (CRC) Generation and Checking**
- **Programmable NRZI Encode/Decode**
- **N-Bit Reception Capability**
- **Digital Phase Locked Loop Clock Recovery**
- **Minimum CPU Overhead**
- **Fully Compatible with 8080/8085 CPUs**
- **Single +5V Supply**
- **40-Pin Package**

The Intel® 8273 Programmable HDLC/SDLC Protocol Controller is a dedicated device designed to support the ISO/C-CITT's HDLC and IBM's SDLC communication line protocols. It is fully compatible with Intel's new high performance microcomputer systems such as the MCS-85™. A frame level command set is achieved by a unique microprogrammed dual processor chip architecture. The processing capability supported by the 8273 relieves the system CPU of the low level real-time tasks normally associated with controllers.

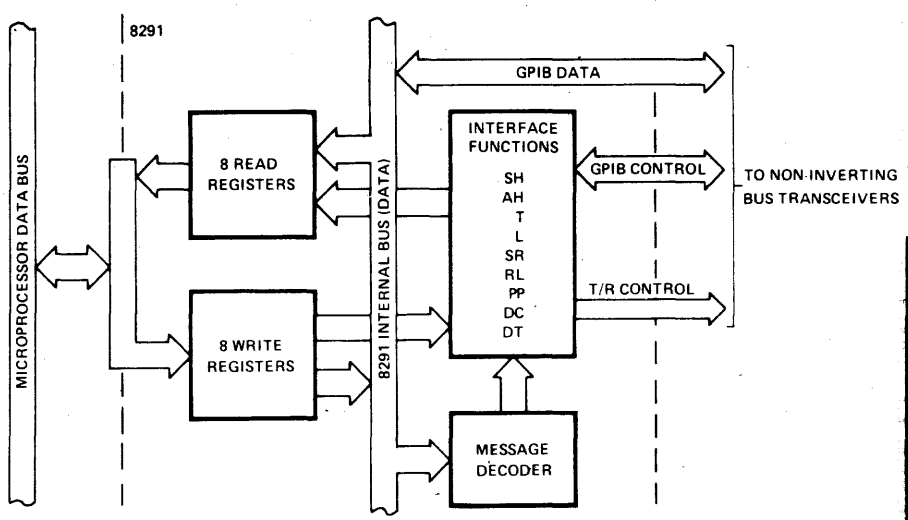
8291
GPIB TALKER/LISTENER



- Designed to Interface Microprocessors (e.g., 8080, 8085, 8086, 8048) to an IEEE Standard 488 Digital Interface Bus
- Programmable Data Transfer Rate
- Complete Source and Acceptor Handshake
- Complete Talker and Listener Functions with Extended Addressing
- Service Request, Parallel Poll, Device Clear, Device Trigger, Remote/Local Functions
- Selectable Interrupts
- On-Chip Primary and Secondary Address Recognition
- Automatic Handling of Addressing and Handshake Protocol
- Provision for Software Implementation of Additional Features
- 1-5 MHz Clock Range
- 16 Registers (8 Read, 8 Write), 2 for Data Transfer, the Rest for Interface Function Control, Status, etc.
- Directly Interfaces to External Non-Inverting Transceivers for Connection to the GPIB
- Provides Three Addressing Modes, Allowing the Chip to be Addressed Either as a Major or a Minor Talker/Listener with Primary or Secondary Addressing
- DMA Handshake Provision Allows for Bus Transfers without CPU Intervention
- Trigger Output Pin
- On-Chip EOS (End of Sequence) Message Recognition Facilitates Handling of Multi-Byte Transfers

The 8291 GPIB Talker/Listener is a microprocessor-controlled chip designed to interface microprocessors (e.g., 8080, 8085, 8086, 8048) to an IEEE Standard 488 Instrumentation Interface Bus. It implements all of the Standard's Talker/Listener interface functions.

8085A/8085A-2
SINGLE CHIP 8-BIT N-CHANNEL MICROPROCESSORS

- **Single +5V Power Supply**
- **100% Software Compatible with 8080A**
- **1.3 μs Instruction Cycle (8085A); 0.8 μs (8085A-2)**
- **On-Chip Clock Generator (with External Crystal, LC or RC Network)**
- **On-Chip System Controller; Advanced Cycle Status Information Available for Large System Control**
- **Four Vectored Interrupt Inputs (One is non-Maskable) Plus an 8080A-compatible interrupt**
- **Serial In/Serial Out Port**
- **Decimal, Binary and Double Precision Arithmetic**
- **Direct Addressing Capability to 64k Bytes of Memory**

The Intel® 8085A is a complete 8 bit parallel Central Processing Unit (CPU). Its instruction set is 100% software compatible with the 8080A microprocessor, and it is designed to improve the present 8080A's performance by higher system speed. Its high level of system integration allows a minimum system of three IC's [8085A (CPU), 8156 (RAM/IO) and 8355/8755A (ROM/PROM/IO)] while maintaining total system expandability. The 8085A-2 is a faster version of the 8085A.

The 8085A incorporates all of the features that the 8224 (clock generator) and 8228 (system controller) provided for the 8080A, thereby offering a high level of system integration.

The 8085A uses a multiplexed data bus. The address is split between the 8 bit address bus and the 8 bit data bus. The on-chip address latches of 8155/8156/8355/8755A memory products allow a direct interface with the 8085A.

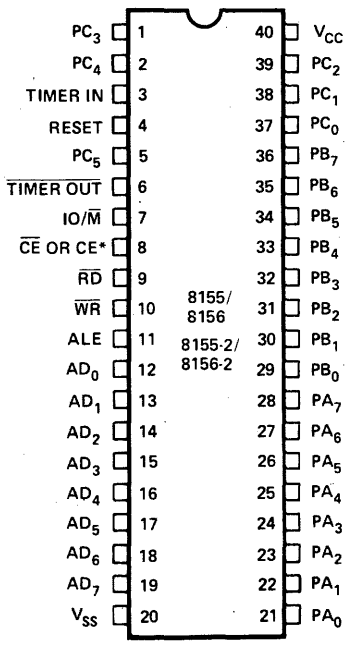
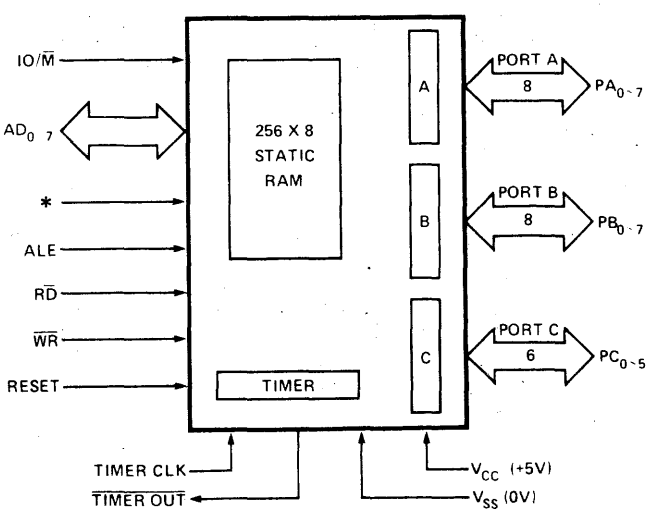
8155/8156/8155-2/8156-2
2048 BIT STATIC MOS RAM WITH I/O PORTS AND TIMER

8085A	8085A-2	Compatible CPU / Chip Enable
8155	8155-2	ACTIVE LOW
8156	8156-2	ACTIVE HIGH



- 256 Word x 8 Bits
- Single +5V Power Supply
- Completely Static Operation
- Internal Address Latch
- 2 Programmable 8 Bit I/O Ports
- 1 Programmable 6-Bit I/O Port
- Programmable 14-Bit Binary Counter/ Timer
- Multiplexed Address and Data Bus
- 40 Pin DIP

The 8155 and 8156 are RAM and I/O chips to be used in the MCS-85™ microcomputer system. The RAM portion is designed with 2048 static cells organized as 256 x 8. They have a maximum access time of 400 ns to permit use with no wait states in 8085A CPU. The 8155-2 and 8156-2 have maximum access times of 330 ns for use with the 8085A-2.



The I/O portion consists of three general purpose I/O ports. One of the three ports can be programmed to be status pins, thus allowing the other two ports to operate in handshake mode.

A 14-bit programmable counter/timer is also included on chip to provide either a square wave or terminal count pulse for the CPU system depending on timer mode.

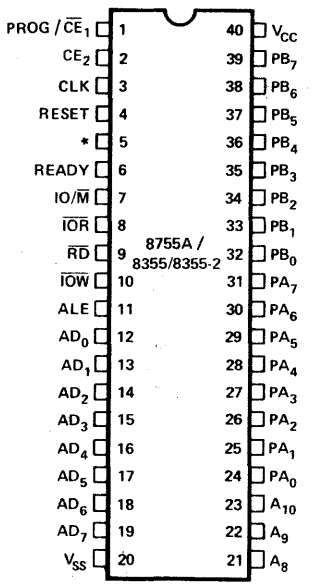
8755A*/8355*/8355-2**
16,384-BIT ROM WITH I/O

***Directly Compatible with 8085A CPU**

****Directly Compatible with 8085A-2**

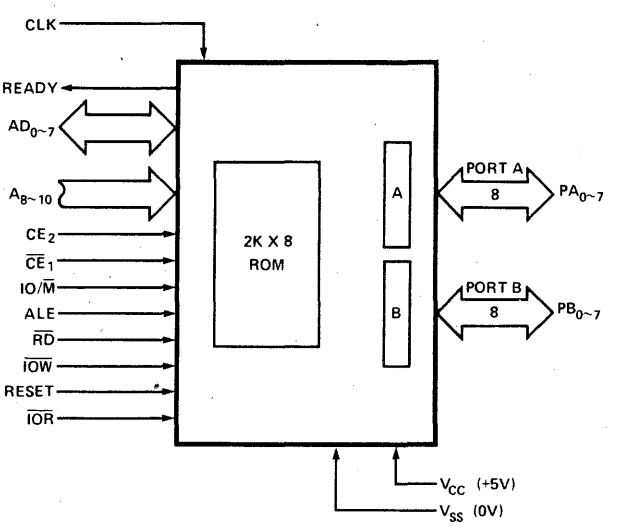
- **2048 Words x 8 Bits**
- **Single +5V Power Supply**
- **Internal Address Latch**
- **2 General Purpose 8-Bit I/O Ports**
- **Each I/O Port Line Individually Programmable as Input or Output**
- **Multiplexed Address and Data Bus**
- **Pin Compatible ROM (8355, 8355-2) and EPROM (8755A) Versions**
- **40-Pin DIP**



The Intel® 8755A is an erasable and electrically reprogrammable ROM (EPROM) and I/O chip to be used in the MCS-85™ microcomputer system. The EPROM portion is organized as 2048 words by 8 bits. It has a maximum access time of 450 ns to permit use with no wait states in an 8085A CPU.

The Intel® 8355 is a ROM and I/O chip to be used in the MCS-85™ microcomputer system. The ROM portion is organized as 2048 words by 8 bits. It has a maximum access time of 400 ns to permit use with no wait states in the 8085A CPU.

The I/O portion consists of 2 general purpose I/O ports. Each I/O port has 8 port lines, and each I/O port line is indivdually programmable as input or output.



The 8355-2 has a 300ns access time for compatibility with the 8085A-2 microprocessor.

8086
16-BIT HMOS MICROPROCESSOR

- **Direct Addressing Capability to 1 MByte of Memory**
- **Assembly Language Compatible with 8080/8085**
- **14 Word, By 16-Bit Register Set with Symmetrical Operations**
- **24 Operand Addressing Modes**
- **Bit, Byte, Word, and Block Operations**
- **8-and 16-Bit Signed and Unsigned Arithmetic in Binary or Decimal Including Multiply and Divide**
- **5 MHz Clock Rate**
- **MULTIBUS™ Compatible System Interface**

The Intel® 8086 is a new generation, high performance microprocessor implemented in N-channel, depletion load, silicon gate technology (HMOS), and packaged in a 40-pin CerDIP package. The processor has attributes of both 8- and 16-bit microprocessors. It addresses memory as a sequence of 8-bit bytes, but has a 16-bit wide physical path to memory for high performance.

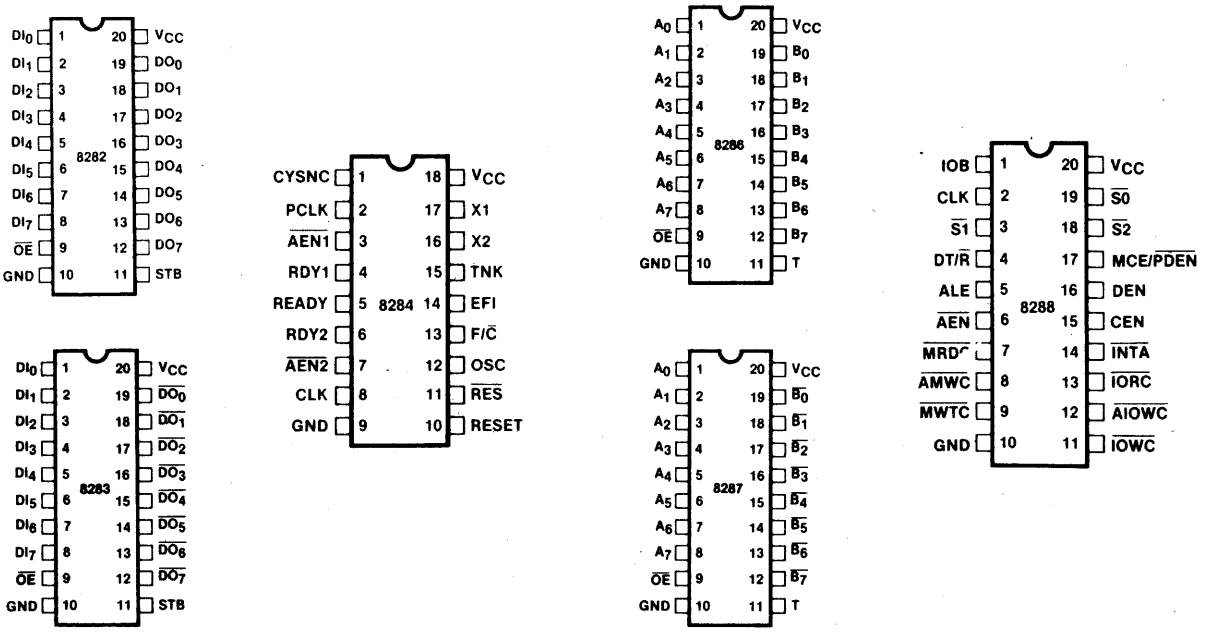
8282/8283/8284/8286/8287/8288 BIPOLAR SYSTEM SUPPORT COMPONENTS FOR MCS-86

- **8282/8283: 8-Bit Latches (3-State, 8283 Inverting)**
- **8284: Clock Generator and Driver for 8080 CPU**
- **8286/8287: 8-Bit Parallel Bidirectional Bus Drivers (3-State, 8287 Inverting)**
- **8288: Bus Controller for 8086 CPU — Generates MULTIBUS™ Compatible Control Signals. Facilitates Interface of 8086 to a Multi-Master Bus.**



The 8282 and 8283 are 8-bit bipolar latches with 3-state output buffers. They can be used to implement latches, buffers, or multiplexers. The 8283 inverts the input data at its outputs while the 8282 does not. Thus, all of the principal peripheral and input/output functions of a microcomputer system can be implemented with these devices.

The 8284 is a bipolar clock generator/driver designed to provide clock signals for the 8086 CPU and peripherals. It also contains READY logic for operation with two MULTIBUS™ systems and provides the 8086's required READY synchronization and timing. Reset logic with hysteresis and synchronization is also provided.

The 8286 and 8287 are 8-bit bipolar transceivers with 3-state outputs. The 8287 inverts the input data at its outputs while the 8286 does not. Thus, a wide variety of applications for buffering in microcomputer systems can be met.

The Intel® 8288 Bus Controller is a 20-pin bipolar component for use with medium-to-large 8086 processing systems. The bus controller provides command and control timing generation as well as bipolar bus drive capability while optimizing system performance.

SDK-86
MCS-86™ SYSTEM DESIGN KIT

- **Complete Single Board Microcomputer System Including CPU, Memory and I/O**
- **Easy to Assemble Kit-Form**
- **High-Performance 8086 16-Bit CPU**
- **Interfaces Directly with TTY or CRT**
- **Interactive LED Display and Keyboard**
- **Wire-Wrap Area for Custom Interfaces**
- **Extensive System Monitor Software in ROM**
- **Comprehensive Design Library Included**

The MCS-86 System Design Kit (SDK-86) is a complete, single board 8086 microcomputer system in kit form. It contains all necessary components, including LED Display, Keyboard, resistors, caps, crystal and miscellaneous hardware to complete construction. Included are preprogrammed ROMs that contain the system monitor for general software utilities and system diagnostics.

The SDK-86 includes 8-digit LED display and a mnemonic 24-key keyboard for direct insertion, examination and execution of a user's program. In addition, it can be directly interfaced with a teletype terminal, CRT terminal, or the serial port of an Intellec® system.

The SDK-86 is a high-performance prototype system that has designed-in flexibility for simple interface to the user's application.

MODEL 230
INTELLEC® SERIES II
MICROCOMPUTER DEVELOPMENT SYSTEM

Complete Microcomputer Development Center for Intel MCS-80™, MCS-85™ and MCS-48™ microprocessor families

Integral CRT with detachable upper/lower case "typewriter-style " full ASCII keyboard

64K bytes RAM memory

1 million bytes (expandable to 2.5M bytes) of diskette storage

LSI electronics board with CPU, RAM, ROM, I/O and interrupt circuitry

Built-in interfaces for High-Speed Paper Tape Reader/Punch, Printer and Universal PROM Programmer

Powerful ISIS-II Diskette Operating System Software with Relocating Macro Assembler, Linker and Locater

"Self-Test" Diagnostic capability

Standard MULTIBUS™ with multiprocessor and DMA capability

Eight-level nested, maskable priority interrupt system

Compatible with standard Intellec/iSBC Expansion Modules

Software compatible with previous Intellec Systems

Supports PL/M and FORTRAN high level languages

The Intellec Series II Model 230 Microcomputer Development System is a complete center for the development of microcomputer-based products. It includes a CPU, 64K bytes of RAM, 4K bytes of ROM memory, a 2000-character CRT, detachable full ASCII keyboard and dual double-density diskette drives providing over 1 million bytes of on-line data storage.

Powerful ISIS-II Diskette Operating System software allows the Model 230 to be used quickly and efficiently for assembly and/or compilation and debugging of programs for Intel's MCS-80, MCS-85 or MCS-48 microprocessor families without the need for handling paper tape. ISIS-II performs all file handling operations for the user, leaving him free to concentrate on the details of his own application. When used in conjunction with an optional in-circuit emulator (ICE™) module, the Model 230 provides all the hardware and software development tools necessary for the rapid development of a microcomputer-based product.

UPP-103*
UNIVERSAL PROM PROGRAMMER

Intellec® Development System Peripheral for PROM programming and verification

Personality cards available for programming all Intel® PROM families

Zero insertion force sockets for both 16-pin and 24-pin PROMs

Universal PROM Mapper software provides powerful data manipulation and programming commands

Flexible power source for system logic and programming pulse generation

Holds 2 personality cards to facilitate programming operations using several PROM types

The Universal PROM Programmer (UPP) is an Intellec® System peripheral capable of programming and verifying the following Intel Programmable ROMs (PROMs): 1702A, 2704, 2708, 2716, 3601, 3602, 3602A, 3621, 3622, 3622A, 3604, 3604A, 3604AL, 3604L-6, 3605, 3608, 3624, 3624A, 3625, 3628, 8702A, 8704, and 8708. In addition, the UPP programs the PROM memory portions of the 8748 Microcomputer and the 8755 PROM and I/O chip. Programming and verification operations are initiated from the Intellec Development System console and are controlled by the Universal PROM Mapper (UPM) program.

*This UPP103 replaces the UPP101, UPP102.

intel®

INTELLEC PROMPT 48
MCS-48 MICROCOMPUTER DESIGN AID

Complete low cost design aid and EPROM programmer for revolutionary MCS-48 single component computers

Simplifies microcomputing, allowing user to enter, run, debug, and save machine language programs with calculator-like ease

Utilizes two removable 8-bit MCS-48 CPUs
- **— 8748 CPU with erasable, reprogrammable on-chip program memory**
- **— 8035 CPU with off-chip program memory**

1K-byte erasable, reprogrammable on-chip (8748), expandable program memory, 1K-byte RAM in PROMPT system

64 bytes RAM on-chip, expandable register memory

256 bytes expandable RAM data memory in PROMPT system

27 on-chip TTL compatible expandable I/O lines

On-chip clock, internal timer/event counter, two vectored interrupts, eight level stack control

Single +5V DC system power requirement

Integral keyboard and displays (no teletypewriter or CRT terminal required)

Extensive PROMPT 48 monitor, allowing system I/O, bus, and memory expansion

Compatible with Intellec microcomputer development systems

Includes comprehensive design library

The Intellec Prompt 48 MCS-48 Microcomputer Design Aid is a low cost, fully-assembled design aid for the revolutionary 8748 single component microcomputer. PROMPT 48 simplifies the programming of MCS-48 systems — programs may be entered and debugged with calculator-like ease on the large, informative display and keyboard panel. The comprehensive design library with tutorial manual is ideal for newcomers to microcomputing. PROMPT 48's panel connector allows easy access to I/O ports and system bus. Thus users can expand program memory beyond the 1K bytes provided internally. PROMPT 48 can serve as an economical 8748 Specialized PROM Programmer (SPP) peripheral in Intellec microcomputer development systems.

©IC MASTER 1979

intel®

ICE-48
MCS-48 IN-CIRCUIT EMULATOR

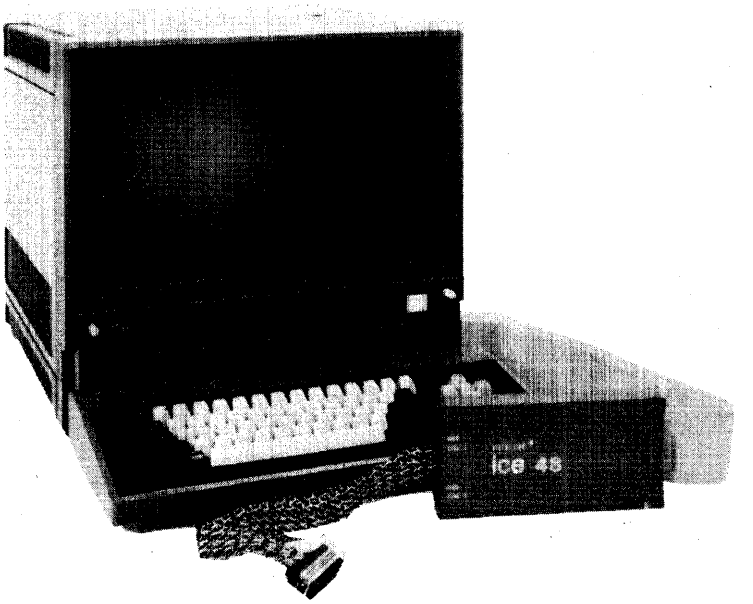
Emulates 8048, 8748, 8035, and 8021 Microcomputers

Extends Intellec microcomputer development system debug power to user configured system via external cable and 40-pin plug, replacing system MCS-48 device

Emulates user system MCS-48 device in real time

Shares static RAM memory with user system for program debug

Provides hardware comparators for user designated break conditions



Eliminates need for extraneous debugging tools residing in user system

Collects bus, register, and MCS-48 status information on instructions emulated

Provides capability to examine and alter MCS-48 registers, memory, and flag values, and to examine pin and port values

Integrates hardware and software efforts early to save development time

The ICE-48 MCS-48 In-Circuit Emulator module is an intellec-resident module that interfaces with any MCS-48 system. The MCS-48 family consists of the 8048, 8748, 8035, and 8021 microcomuters. The ICE-48 module interfaces with an MCS-48 system through a cable terminating in an MCS-48 pin-compatible plug which replaces the MCS-48 device in the system. With the ICE-48 plug in place, the designer has the capability to execute the system in real time while collecting up to 255 instruction cycles of real-time trace data. In addition, he can single step the system program to monitor more closely the program logic during execution. Static RAM memory is available through the ICE-48 module to emulate MCS-48 program and data memory. The designer can display and alter the contents of data and replacement RAM control memory, internal MCS-48 registers and flags, and I/O ports. Powerful debug capability is extended into the MCS-48 system while ICE-48 debug hardware and software remain inside the Intellec system. Symbolic reference capability allows the designer to use meaningful symbols rather than absolute values when examining and modifying memory, registers, flags, and I/O ports in this system.

©IC MASTER 1979

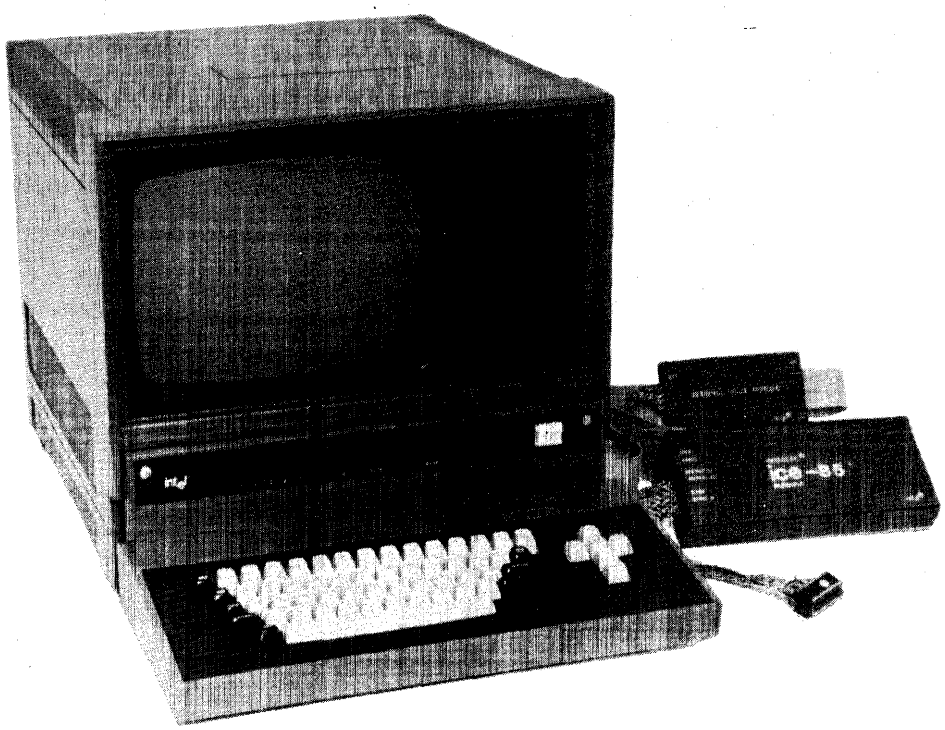
ICE-85™
MCS-85™ IN-CIRCUIT EMULATOR

Connects the Intellec® System Resources to the user-configured system via a 40-pin adaptor plug

Executes user system software in real-time

Allows user-configured system to share Intellec® memory and I/O facilities

Provides 1023 states of 8085 trace data plus 18 additional logic signals via an External Trace Module



Offers full symbolic debugging capability for both assembly language and Intel's high-level compiler language, PL/M-80

Displays trace data from the user's 8085 in assembler mnemonics and allows personality groupings of data sampled by the external 18-channel trace module

Extends ICE capabilities to the rest of the prototype system peripheral circuitry by allowing the user to execute his own peripheral chip analysis routines

Provides ability to examine and alter MCS-85™ registers, memory, flag values, interrupt bits and I/O ports

The ICE-85 module resides in the Intellec® Microcomputer Development System and interfaces to the user system's 8085. In addition, an external trace module provides access to user system peripheral circuitry via a user-configured DIP clip for peripheral ICs or may be attached to as many as 18 separate prototype signal nodes via individual probe clips. Using the ICE-85 module, the designer can execute prototype software in real-time or single-step mode and can substitute Intellec® system memory and I/O for user system equivalent. ICE capability can be extended to the rest of the user system peripheral circuitry by allowing the user to create and execute a library of user-defined peripheral chip analyzer routines. All user access to the prototype system software may be done symbolically by assigning names to program locations and data, I/O ports and groups of external trace signals. For the first time, in-circuit emulation extends beyond the user's prototype CPU to the entire user's system, allowing In-System Emulation.

©IC MASTER 1979

PL/M-80
HIGH LEVEL PROGRAMMING LANGUAGE
INTELLEC® RESIDENT COMPILER

Cuts software development and maintenance costs

Speeds project completion

Improves product reliability

Eases enhancements as system capabilities expand

Produces relocatable and linkable object code

Resident operation on Intellec® Microcomputer Development System and Intellec® Series II Microcomputer Development Systems

Sophisticated code optimization reduces application memory requirements

PL/M-80 is an advanced, high-level programming language for Intel® 8080 and 8085 Microprocessors, iSBC-80 OEM Computer Systems and Intellec® Microcomputer Development Systems. PL/M has been substantially enhanced since its introduction in 1973 and has become one of the most effective and powerful microprocessor systems implementation tools available. It is easy to learn, facilitates rapid program development and debugging, and significantly reduces maintenance costs.

PL/M is a powerful, high-level algorithmic language in which program statements can naturally express the algorithm to be programmed. This frees programmers to concentrate on their system development without having to deal with assembly language details (such as register allocation, meanings of assembler mnemonics, etc.).

The PL/M compiler efficiently converts free-form PL/M programs into equivalent 8080/8085 instructions. Substantially fewer PL/M statements are necessary for a given application than if it were programmed at the assembly language or machine code level.

Since PL/M programs are problem oriented and more compact, programming in PL/M results in a high degree of productivity during development efforts. This translates into significant reductions in software development and maintenance costs for the user.

FORTRAN-80
8080/8085 ANS FORTRAN 77
INTELLEC RESIDENT COMPILER

Provides resident operation on Intellec Microcomputer Development System and Intellec Series II microcomputer development systems

Meets and exceeds ANS FORTRAN 77 Subset Language Specification

Produces relocatable and linkable object code compatible with resident PL/M-80 and 8080/8085 macroassembler

Supports Intel floating point standard

Provides full FORTRAN 77 language I/O support when used with ISIS-II runtime library

Sophisticated code optimization insures efficient program implementation

Supports full symbolic debugging with ICE-80 and ICE-85

FORTRAN-80 is a computer industry standard, high level programming language and compiler that translates FORTRAN statements into relocatable object modules. When the object modules are linked together and located into absolute program modules, they are suitable for execution on Intel 8080/8085 microprocessors, iSBC-80 OEM computer systems, and Intellec microcomputer development systems. FORTRAN-80 meets and exceeds the ANS FORTRAN 77 Language Subset Specification[1]. The compiler operates on Intellec microcomputer development systems under ISIS-II disk operating systems and produces efficient relocatable object modules compatible for linkage with PL/M-80 and 8080/8085 macroassembler modules. The ANS FORTRAN 77 language specification offers many powerful extensions to the FORTRAN language that are especially well suited to Intel 8080/8085 microprocessor software development. Because FORTRAN-80 conforms to the ANS FORTRAN 77 standard, the user is assured of compatibility with existing FORTRAN software meeting the standard as well as a guarantee of upward compatibility to other computer systems supporting an ANS FORTRAN 77 compiler.

[1] ANSI X3J3/90

©IC MASTER 1979

MCS-48™ DISKETTE-BASED SOFTWARE SUPPORT PACKAGE

Extends Intellec® Microcomputer Development System to support MCS-48™ development

MCS-48 Assembler provides conditional assembly and macro capability

Takes advantage of powerful ISIS-II file handling and storage capabilities

The MCS-48™ Diskette-based Software Support Package (MDS-D48) comes on an Intel® ISIS-II System Diskette and contains the MCS-48 Assembler (ASM48), and the diskette version of the Universal PROM Mapper.

The MCS-48 Assembler (ASM48) translates symbolic 8048 assembly language instructions into the appropriate machine operation codes. In addition to eliminating the errors of hand translation, the ability to refer to program addresses with symbolic names makes it easier to modify programs when adding or deleting instructions. Conditional assembly permits the programmer to specify portions of the master source document which should be included or deleted in variations on a basic system design, such as the code required to handle optional external devices.

Macro capability allows the programmer to define a routine through the use of a single label. ASM48 will assemble the code required by the reserved routine whenever the Macro label is inserted in the text.

Output from the ASM48 is in standard Intel® Hex format. It may be loaded directly to an ICE-48 module for integrated hardware/software debugging. It may also be loaded into the Intellec Development System for 8748 PROM programming using the Universal PROM Programmer.

MDS-EM1 8021 EMULATION BOARD

EPROM functional equivalent of 8021 — single component 8-bit microcomputer

Based on 8748 — user programmable/erasable EPROM 8-bit computer

Operates with ICE-48™ to provide full in-circuit debugging of 8021 prototype system

Connects to prototype system through 8021 pin compatible plug

On-card 3.0 MHz or external TTL driven clock

Portable 4" × 7" microcomputer circuit assembly

The MDS-EM1 emulator board is a ready-to-use 4" × 7" microcomputer circuit assembly that emulates the Intel 8021 microcomputer. A 12-inch flat-cable assembly connects the board to the 8021 socket in a prototype system. The board is designed so that it can be mounted either as a stand-alone unit, or within the prototype assembly.

The 8021 microcomputer has 1K × 8 mask-programmable ROM program memory and 64 by 8 RAM data memory. The MDS-EM1 is controlled by an Intel 8748, with 1K of EPROM program memory and a 64 byte data memory. The EPROM can be programmed and erased repeatedly during hardware and software development. The MDS-EM1 has several ancillary circuits that perform the following functions which are specific to the 8021:

Zero crossing detector

Crystal controlled clock/buffer

Port Ø simulator

For prototype debugging, the 8748 can be removed from its socket and replaced with a cable to an INTEL ICE-48. When used with the MDS-EM1, ICE-48 emulates the 8021 in real-time, or single-steps the 8021 program at the user's command. A full range of capabilities for examining and modifying 8021 memory and status are supplied through ICE-48.

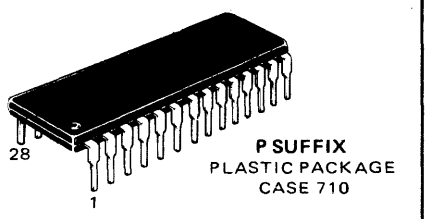
ONE CHIP MICROCOMPUTERS



ONE CHIP MICROCOMPUTERS

The MC141000 family is a series of 4-bit CMOS Microcomputers designed for dedicated applications. The CMOS technology of the MC141000 family provides the flexibility of microcomputers, for battery-powered and battery-backed-up applications. The MC141000 and MC141200 include ROM, RAM, and I/O for self-contained configurations in 28 and 40-pin packages. The 48-pin MC141099 has RAM and I/O with provision for external program memory. The MC141099 serves lower-volume applications such as prototyping or pilot production of MC141000 and MC141200 systems.

MAXIMUM RATINGS (Voltages referenced to V_{SS})

Rating	Symbol	Value	Unit
DC Supply Voltage	V_{DD}	-0.5 to +6.5	Vdc
Input Voltage, All Inputs	V_{in}	-0.5 to V_{DD} + 0.5	Vdc
DC Current Drain per Pin, All Inputs	I	10	mAdc
DC Current Drain, V_{DD} Pin	I	250	mAdc
DC Current Drain, V_{SS} Pin	I	20	mAdc
Operating Temperature Range	T_A	-40 to +85	°C
Storage Temperature Range	T_{stg}	-65 to +150	°C
Total Power Dissipation	P_D	See Figure 1	mW

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. For proper operation it is recommended that V_{in} and V_{out} be constrained to the range $V_{SS} \leq (V_{in} \text{ or } V_{out}) \leq V_{DD}$.

RECOMMENDED OPERATING CONDITIONS (V_{SS} = 0)

Parameter	Symbol	Value	Unit
DC Supply Voltage — High Speed Clock Full Range Operation	V_{DD}	+4.75 to +6.0 +3.0 to +6.0	Vdc
Clock Frequency — V_{DD} = 5.0 Vdc ± 5% V_{DD} = 3.0 Vdc Min.	f_{Clk}	DC to 600 DC to 200	kHz

ELECTRICAL CHARACTERISTICS (V_{DD} = +5.0 V, V_{SS} Gnd, T_A = 25°C unless otherwise noted)

Characteristic	Symbol	Min	Typ	Max	Unit
Input Current — K Inputs and INIT	I_{in}				μAdc
(V_{in} = 5.0 V)		75	100	135	
(V_{in} = 0.0 V)		–	-0.00001	-0.3

FIGURE 4 – FUNCTIONAL BLOCK DIAGRAM – MC141000/MC141200/MC141099

The block diagram above shows the resources available to the MC141000/1200/1099 programmer. They are:

A The accumulator is used to store the result of an ALU operation for subsequent operations.

ALU The arithmetic logical unit performs calculation and decision-making tasks.

K Inputs The K lines are the data input port. Since there are only four input lines, they are usually multiplexed under control of the R lines. The inputs are diode protected and have a pull-down resistor of approximately 50 kΩ; therefore, open inputs are read as a logic low.

O Outputs The eight outputs of the PLA are connected to output drivers which comprise the O outputs. These output drivers may be manufactured as open emitter, active sink, or push-pull at the user's option.

PLA The output programmable logic array is user-defined to specify the state of each of the eight O outputs for each of the 32 possible PLAIR outputs.

PLAIR The programmable logic array input register is a 5-bit latch which latches the four accumulator bits and the output of the status latch.

RAM Variable data is stored in the 64-word, 4-bit per word Random Access Memory. Data is accessed by decoding a 2-bit file address (X register) and 4-bit word address (Y register).

ROM Array The user's instructions are mask programmed into the Read Only Memory (ROM). Instructions are addressed by a page address register (PA) and program counter (PC). A single subroutine return register (SRR) and page buffer register (PB) permit a subroutine call to any location within the ROM.

R Outputs The output of the Y register is decoded to select one of the R-output lines which can then be set or reset under program control. The R lines are used as control lines to scan keyboards and displays, perform handshakes, and interface external logic. The R outputs may be manufactured as open emitter, active sink, or push-pull at the user's option.

S All branches and subroutine calls are dependent on the state of status logic. It may be set or reset on logical or arithmetic operations and is set by the remainder of the instructions.

SL The status latch stores the state of the status logic in order to preserve it for subsequent O output operations.

NOTE: S and SL are NOT identical.

Y Register The Y register is a multipurpose regiser used to address a word in a RAM file, to select an R output for manipulation by subsequent instructions, or as a general-purpose counting and storage register.

©IC MASTER 1979

MICROCOMPUTER OPERATION

The MC141000/1200/1099 program controls data input, storage, processing, and output. The microcomputer internal organization is shown in Figure 4. The processing of data occurs in the arithmetic logic unit (ALU). K-input data enters the ALU and is stored in the 4-bit accumulator. The accumulator output accesses the output latches, RAM storage, or the ALU input. Data is stored in the 256-bit RAM, organized into 64 words, 4 bits per word. The 4-bit words are grouped into four 16-word files addressed by a 2-bit X register. The 4-bit Y register addresses one of the 16 words in a file.

The 43 basic instructions handle I/O, constant data from the ROM, bit control, internal data transfer, arithmetic processing, logic comparison, conditional and nonconditional branching and subroutines.

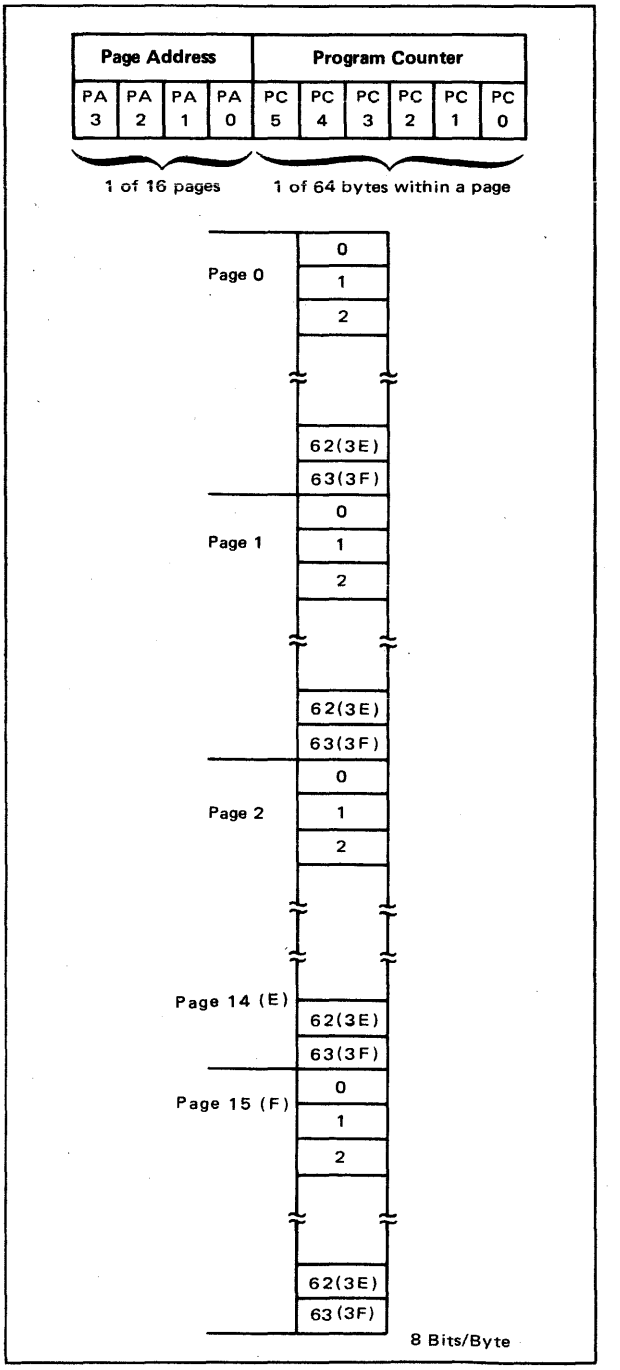
The system designer has access for mask programming the following functions:

1. ROM – 1024 Words of 8 Bits
2. Programmable Logic Array for O Outputs
3. Output Drivers

The MC141000 microcomputer consists of seven subsystems:

1. Read Only Memory (ROM)
2. Random Access Memory (RAM)
3. Output Ports
4. Input Port
5. Arithmetic Logical Unit (ALU)
6. The Instruction Decoder
7. Clock

The following paragraphs describe how each of these subsystems is controlled by the instruction set. Every instruction occupies a single memory byte and is executed in one instruction cycle (six clock cycles).



ROM ARRAY

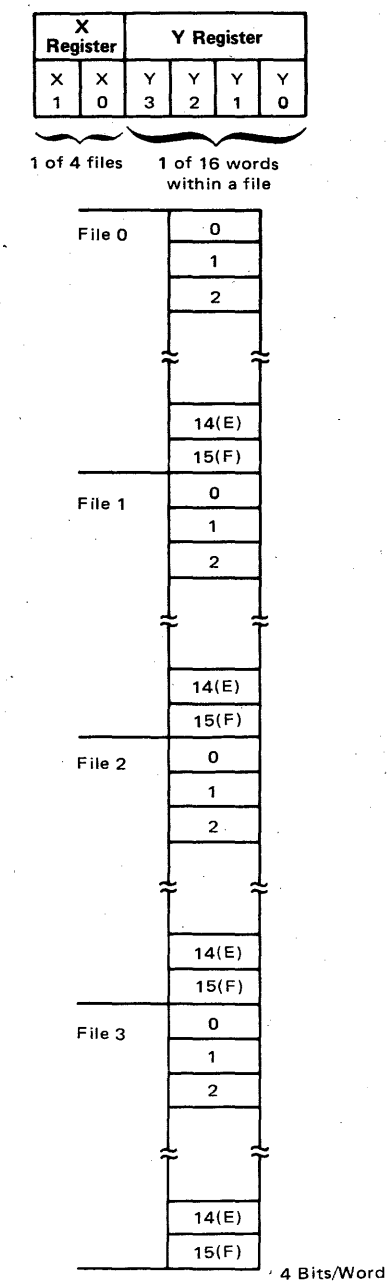
The ROM in the MC141000/1200 consists of 8192 bits of mask-programmed memory organized as 1024 8-bit instructions. It is divided into 16 pages of 64 instructions per page. See Figure 5.

Instructions within ROM are addressed by the page address register (PA) which contains the page number, and the program counter (PC) which contains the location of the instruction relative to the beginning of the page. The PC is incremented prior to fetching the next instruction (unless diverted by a BRanch or CALL) so each instruction is accessed in the numerical order of its address. A carry from the PC is not added to the PA so the program "wraps around" within the page rather than executing the first instruction of the following page. Upon power up, the PC is set to zero and the PA and PB are set to 15.

The MC141099 addresses an external ROM program via ten address output lines. These are 6 bits from PC (PC0–PC5) and 4 bits from PA (PA0–PA3). The 8-bit instruction bytes are received by the MC141099 from an external ROM on 8 TTL compatible instruction input lines (I0–I7).

FIGURE 5 – ROM ORGANIZATION

©IC MASTER 1979



RANDOM ACCESS MEMORY – RAM

RAM consists of 256 bits organized into 64 4-bit words. For purposes of addressing, the 4-bit words are organized into four files of 16 4-bit words per file, Figure 6.

The X register is decoded to select 1 of the 4 RAM files; and the Y register is decided to address 1 of the 16 words in the selected file.

Individual bits within the RAM can be set, reset and tested under program control.

FIGURE 6 – RAM ORGANIZATION

OUTPUT PORTS

Two output ports (R and O) are included in the microcomputer. The MC141000 has eleven R outputs and the MC141200 and MC141099 each have sixteen R outputs. The MC141000 and MC141200 each have eight O outputs, while the MC141099 has five. The number of R outputs is the only difference between the MC141000 and the MC141200.

R-output lines are used primarily as control or "handshake" lines, and to multiplex external hardware. The R output which is to be operated on is selected by a binary decode of the contents of the Y register. Set R and reset R instructions change the state of one R output at a time.

The eight O-output lines on the MC141000 and MC141200 are the decoded outputs of the contents of the 5-bit PLAIR. Since the PLAIR is loaded from the A and the SL, these registers must be "set up" prior to an output operation. The status latch can only be loaded by the YNEA (Y register not equal to accumulator) instruction while the contents of the accumulator may be modified by numerous other instructions. The MC141099 brings out the 5-bit PLAIR to allow external decoding. An external PROM/EPROM could be used to simulate the PLA. Figure 7 shows how EPROMS may be used with MC141099 to emulate an MC14100 or an MC141200.

In a typical application, the first four R lines might be used as digit selects for outputting a four-digit decimal number using the PLA programmed as a seven-segment decode as shown in Figure 8.

The MC141000/1200 outputs may be mask programmed in any of three configurations. Figure 9 shows the open emitter circuit capable of sourcing 20 mA at V_O = 2.4 V and V_{DD} = 5.0 V, which will drive an LED. Figure 10 is the open drain circuit capable of sinking 1.6 mA over temperature, which will drive one TTL load or four LSTTL loads. The source and sink devices are combined in the active push-pull circuit of Figure 11. The MC141099 also has outputs as in Figure 11.

INPUTS

The input lines consist of the four K-input lines and the initialize (INIT) line. All inputs are static-protected CMOS inputs with pulldown of about 50 kΩ. Thus, an open input is equivalent to logic 0. The circuit is shown in Figure 12.

When power is applied, the registers shown in Table 1 are loaded as shown for power up. All other internal registers and RAM come up in an arbitrary state.

After power is applied, the initialize (INIT) input may be used to reinitialize the processor. Internally, INIT has

TABLE 1 – POWER UP AND INITIALIZE CONDITIONS

	PC	PA	PB	CL	PLAIR	R Outputs
Power Up	0	F_{16}	F_{16}	0	0	0
Initialize	0	$\overline{K}$	$\overline{K}$	0	0	0

©IC MASTER 1979

a 50 kΩ pull-down resistor which holds the INIT line low. It must be held high for a minimum of 6 full clock cycles and then returned to the low state. If a mechanical switch or other mechanical device is used to control INIT, it may be necessary to include a method of contact debounce to ensure a valid INIT pulse.

A valid INIT pulse causes the registers to be initialized as shown in the table. The contents of registers other than those shown remain unchanged during initialize. Note that the PA and PB are loaded with the 1's complement of the K-input lines (K8 = MSB). This feature allows the MC141000 to be initialized to the first instruction on any page by controlling the K inputs. This is useful where the same circuit may be used for several applications. Since the K inputs have 50 kΩ pull-down resistors, open inputs are a 0 (unless driven from another device) and the 1's complement (F_{16}) is loaded into PA and PB.

ARITHMETIC LOGICAL UNIT (ALU)

The ALU is the calculating and decision-making portion of the MC141000/1200/1099 hardware and consists of a 4-bit adder/comparator and the status logic.

The adder/comparator can add, subtract, compare two numbers, add +1, −1, 6, 8, and 10.

The status logic is selectively set or reset by add, subtract, increment, decrement, compare and bit-test operations. Other instructions always set the status logic to a 1.

INSTRUCTION DECODE

The instruction decode logic latches every instruction fetched from ROM and configures the internal logic to execute the current instruction. The instruction set is listed in Table 2.

CLOCK

The internal oscillator cirucit operates with quartz crystals, ceramic resonators, an external resistor and from an external clock source. These oscillator circuit connections are shown in Figures 13, 14, and 15. Figure 16 shows the typical oscillation frequency with an external resistor. The discrete component values used with the quartz crystal and ceramic resonator oscillators may vary depending upon crystal/resonator manufacturer.

TABLE 2 – MC141000/1200/1099 INSTRUCTION SET

Opcode	Mnemonic	Description
0111 (C)	ALEC	If accumulator is less than or equal to I(C) field, status = 1.
00101001	ALEM	If accumulator is less than or equal to M(X,Y), status = 1.
00100101	AMAAC	Add memory to accumulator. Accumulator = result, status = carry.
00000110	A6AAC	Add 6 to accumulator. Accumulator = result, status = carry.
00000001	A8AAC	Add 8 to accumulator. Accumulator = result, status = carry.
00000101	A10AAC	Add 10 to accumulator. Accumulator = result, status = carry.
10 (W)	BR	Branch to label if status = 1.
11 (W)	CALL	Call subroutine if status = 1.
00101111	CLA	Clear contents of accumulator.
00001011	CLO	Clear PLA Input Register.
00000000	COMX	Complement X-Register.
00101101	CPAIZ	Complement accumulator, then add 1. If accumulator = 0, status = 1.
00000111	DAN	Decrement accumulator. If no borrow, status = 1.
00101010	DMAN	Load M(X, Y) into accumulator and decrement. If no borrow, status = 1.
00101100	DYN	Decrement Y-register. If no borrow, status = 1.
00001110	IA	Increment accumulator.
00101000	IMAC	Load M(X, Y) into accumulator and increment. Status = carry.
00101011	IYC	Increment Y-Register. Status = carry.
00001001	KNEZ	If K-inputs not equal to zero, status = 1.
0001 (C)	LDP	Load page buffer with I(C) field.
001111 (B)	LDX	Load X-register with I(B) field.
00100110	MNEZ	If M(X, Y) not equal to zero, status = 1.
001101 (B)	RBIT	Reset bit I(B) of M(X,Y).
00001111	RETN	Return from subroutine.
00001100	RSTR	Reset R-line specified by Y-register.
00100111	SAMAN	Subtract accumulator from memory. Accumulator = result. If no borrow, status = 1.
001100 (B)	SBIT	Set Bit I(B) of M(X,Y).
00001101	SETR	Set R-line specified by Y-register.
00000011	TAM	Transfer accumulator contents to M(X,Y).
00100000	TAMIY	Transfer accumulator contents to M(X,Y), increment Y-register.
00000100	TAMZA	Transfer accumulator contents to M(X,Y), zero accumulator.
00100100	TAY	Transfer accumulator contents to Y-register.
001110 (B)	TBIT1	If bit I(B) of M(X,Y) is one, status = 1.
0100 (C)	TCY	Transfer I(C) field to Y-register.
0110 (C)	TCMIY	Transfer I(C) field to M(X,Y), increment Y-register.
00001010	TDO	Transfer status latch and accumulator to PLA input register.
00001000	TKA	Tranfer K-inputs to accumulator.
00100001	TMA	Transfer M(X,Y) to accumulator.
00100010	TMY	Transfer M(X,Y) to Y-register.
00100011	TYA	Transfer Y-register contents to accumulator.
00101110	XMA	Exchange contents of M(X,Y) and accumulator.
00000010	YNEA	If Y-register is not equal to accumulator, status and status latch = 1.
0101 (C)	YNEC	If Y-register is not equal to I(C) field, status = 1.

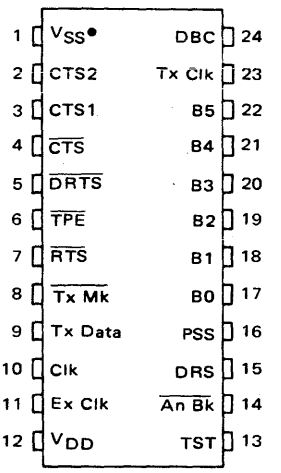
MC6862C

(-40 to 85°C; L Suffix only)

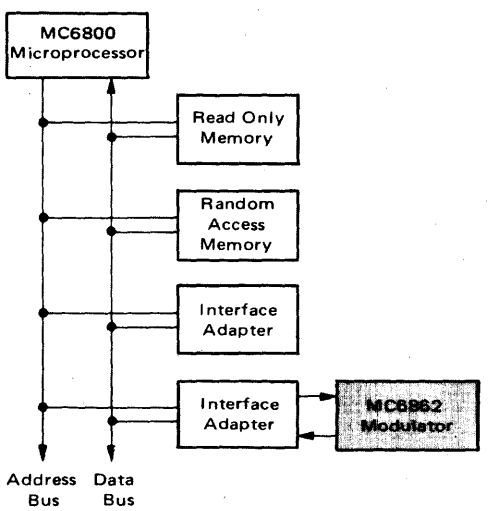
2400 bps DIGITAL MODULATOR

The MC6862 is a MOS subsystem designed to be integrated into a wide range of equipment utilizing serial data communication.



The modulator provides the necessary modulation and control functions to implement a serial data communication link over a voice grade channel, utilizing differential phase shift keying (DPSK) at bit rates of 1200 or 2400 bps. Phase options are provided for both the U.S. and international markets. The MC6862 can be implemented into a wide range of data handling systems, including stand-alone modems, data storage devices, remote data communication terminals, and I/O interfaces for counters.

N-channel silicon gate technology permits the MC6862 to operate using a single voltage supply and be fully TTL compatible.



The modulator is compatible with the M6800 microcomputer family, and provides medium-speed data communications capability.

- Clear-to-Send Delay Options
- 511-Bit CCITT Test Pattern
- Terminal Interfaces Are TTL Compatible
- Compatible Functions for 201B/C Data Sets
- CCITT and U.S. Phase Options
- 1200/2400 bps Operation
- Answer Back Tone

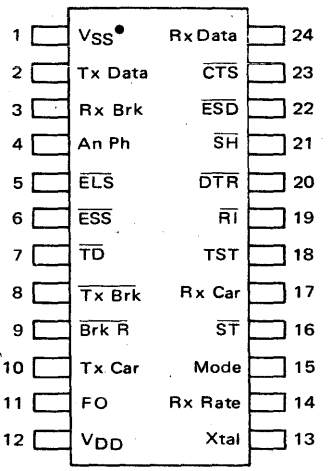
MC6860L

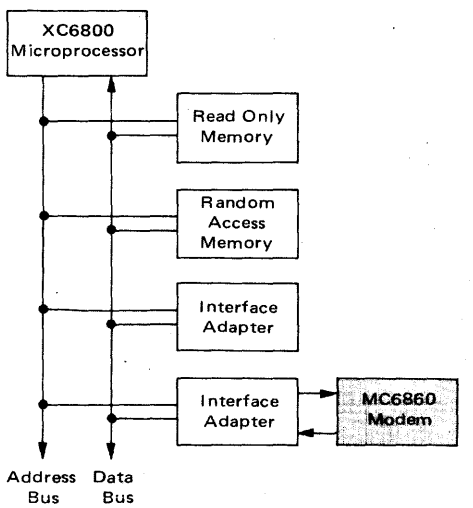
0-600 bps DIGITAL MODEM

The MC6860 is a MOS subsystem designed to be integrated into a wide range of equipment utilizing serial data communications.



The modem provides the necessary modulation, demodulation and supervisory control functions to implement a serial data communications link, over a voice grade channel, utilizing frequency shift keying (FSK) at bit rates up to 600 bps. The MC6860 can be implemented into a wide range of data handling systems, including stand alone modems, data storage devices, remote data communication terminals and I/O interfaces for minicomputers.

N-channel silicon gate technology permits the MC6860 to operate using a single voltage supply and be fully TTL compatible.



The modem is compatible with the M6800 microcomputer family, interfacing directly with the Asynchronous Communications Interface Adapter to provide low-speed data communications capability.

- Originate and Answer Mode
- Crystal or External Reference Control
- Modem Self Test
- Terminal Interfaces TTL-Compatible
- Full-Duplex or Half-Duplex Operation
- Automatic Answer and Disconnect
- Compatible Functions for 100 Series Data Sets
- Compatible Functions for 1001A/B Data Couplers

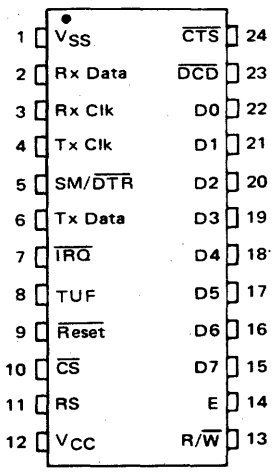
SYNCHRONOUS SERIAL DATA ADAPTER (SSDA)



The MC6852 Synchronous Serial Data Adapter provides a bi-directional serial interface for synchronous data information interchange. It contains interface logic for simultaneously transmitting and receiving standard synchronous communications characters in bus organized systems such as the M6800 Microprocessor systems.

The bus interface of the MC6852 includes select, enable, read/write, interrupt, and bus interface logic to allow data transfer over an 8-bit bi-directional data bus. The parallel data of the bus system is serially transmitted and received by the synchronous data interface with synchronization, fill character insertion/deletion, and error checking. The functional configuration of the SSDA is programmed via the data bus during system initialization. Programmable control registers provide control for variable word lengths, transmit control, receive control, synchronization control, and interrupt control. Status, timing and control lines provide peripheral or modem control.

Typical applications include floppy disk controllers, cassette or cartridge tape controllers, data communications terminals, and numerical control systems.

- Programmable Interrupts from Transmitter, Receiver, and Error Detection Logic
- Character Synchronization on One or Two Sync Codes
- External Synchronization Available for Parallel-Serial Operation
- Programmable Sync Code Register
- Up to 600 kbps Transmission
- Peripheral/Modem Control Functions
- Three Bytes of FIFO Buffering on Both Transmit and Receive
- Seven, Eight, or Nine Bit Transmission
- Optional Even and Odd Parity
- Parity, Overrun, and Underflow Status

MC68488

GENERAL PURPOSE INTERFACE ADAPTER

The MC68488 GPIA provides the means to interface between the IEEE488 standard instrument bus and the MC6800. The 488 instrument bus provides a means for controlling and moving data from complex systems of multiple instruments.

The MC68488 will automatically handle all handshake protocol needed on the instrument bus.

- Single or dual primary address recognition
- Secondary address capability
- Complete source and acceptor handshakes
- Programmable interrupts
- RFD holdoff to prevent data overrun
- Operates with DMA controller
- Serial and parallel polling capability
- Talk-only or listen-only capability
- Selectable automatic features to minimize software
- Synchronization trigger output
- M6800 bus compatible

(Replaces NP-69)

GENERAL DESCRIPTION

The IEEE 488 instrument bus standard is a bit-parallel, byte-serial bus structure designed for communication to and from intelligent instruments. Using this standard, many instruments may be interconnected and remotely and automatically controlled or programmed. Data may be taken from, sent to, or transferred between instruments. A bus controller dictates the role of each device by making the attention line true and sending talk or listen addresses on the instrument bus data lines; those devices which have matching addresses are activated. Device addresses are set into each GPIA from switches or jumpers on a PC board by a microprocessor as a part of the initialization sequence.

When the controller makes the attention line true, instrument bus commands may also be sent to single or multiple GPIA's.

Information is transmitted on the instrument bus data lines under sequential control of the three handshake lines. No step in the sequence can be initiated until the previous step is completed. Information transfer can proceed as fast as the devices can respond, but no faster than the slowest device presently addressed as active. This permits several devices of different speeds to receive the same data concurrently.

The GPIA is designed to work with standard 488-bus driver IC's (MC3448A's) to meet the complete electrical specifications of the IEEE 488 bus. Additionally, a powered-off instrument may be powered-on without disturbing the 488 bus. With some additional logic, the GPIA could be used with other microprocessors.

The MC68488 GPIA has been designed to interface between the MC6800 microprocessor and the complex protocol of the IEEE 488 instrument bus. Many instrument bus protocol functions are handled automatically by the GPIA and require no additional MPU action. Other functions require minimum MPU response due to a large number of internal registers conveying information on the state of the GPIA and the instrument bus.

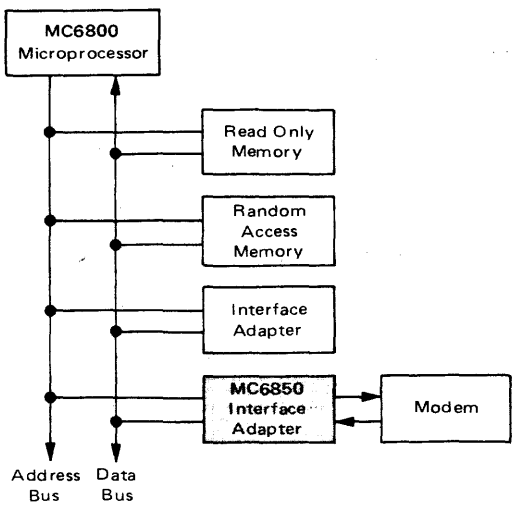
ASYNCHRONOUS COMMUNICATIONS INTERFACE ADAPTER (ACIA)

The MC6850 Asynchronous Communications Interface Adapter provides the data formatting and control to interface serial asynchronous data communications information to bus organized systems such as the MC6800 Microprocessing Unit.



The bus interface of the MC6850 includes select, enable, read/write, interrupt and bus interface logic to allow data transfer over an 8-bit bi-directional data bus. The parallel data of the bus system is serially transmitted and received by the asynchronous data interface, with proper formatting and error checking. The functional configuration of the ACIA is programmed via the data bus during system initialization. A programmable Control Register provides variable word lengths, clock division ratios, transmit control, receive control, and interrupt control. For peripheral or modem operation three control lines are provided. These lines allow the ACIA to interface directly with the MC6860L 0-600 bps digital modem.

- Eight and Nine-Bit Transmission
- Optional Even and Odd Parity
- Parity, Overrun and Framing Error Checking
- Programmable Control Register
- Optional ÷1, ÷16, and ÷64 Clock Modes
- Up to 500 kbps Transmission
- False Start Bit Deletion
- Peripheral/Modem Control Functions
- Double Buffered
- One or Two Stop Bit Operation

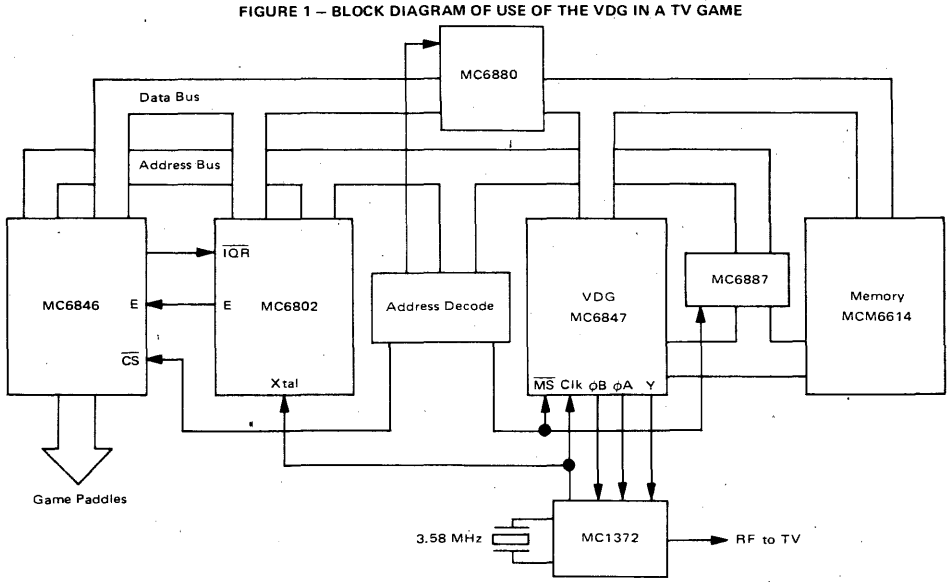
VIDEO DISPLAY GENERATOR (VDG)

The Motorola MC6847 Video Display Generator (VDG) provides a means of interfacing the Motorola M6800 microprocessor family (or similar products) to a commercially available color or black and white television receiver. Applications of the VDG include video games, bioengineering displays, education, communications and any place graphics are required.



The VDG reads data from memory and produces a composite video signal which will allow the generation of alphanumeric or graphic displays. The generated composite video may be up modulated to either Channel 3 or 4 by using the compatible MC1372 (TV Chroma and Video modulator). The up modulated signal is suitable for application to the antenna of a color TV. A typical TV game is indicated in Figure 1.

PIN ASSIGNMENT

- Generates four different alphanumeric display modes and eight graphic display modes
- Compatible with the M6800 family
- Compatible with the MC1372 modulator
- The alphanumeric modes display 32 characters per line by 16 lines
- An internal multiplexer allows the use of either the internal ROM or an external character generator
- An external character generator can be used to extend the internal character set for "limited graphic" shapes
- A Mask Programmable internal character generator ROM is available on special order (Appendix A)
- One display mode offers 8-color 64 x 32 density graphics in an alphanumeric display mode
- One display mode offers 4-color 64 x 48 density graphics in an alphanumeric display mode
- All alphanumeric modes have a selectable video inverse
- Generates full composite video signal
- Generates R-Y and B-Y signals for external color modulator
- Full-graphic modes offer 64 x 64, 128 x 64, 128 x 96, 128 x 192, or 256 x 192 densities
- Full-graphic modes allow 2-color or 4-color data structures
- Full-graphic modes use one of two 4-color sets or one of two 2-color sets
- Available in either an interlace mode (NTSC Standard) or a non-interlace mode

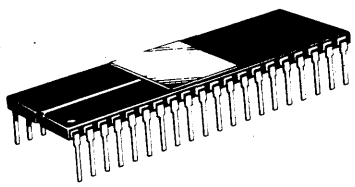
MC6846

ROM–I/O–TIMER

The MC6846 combination chip provides the means, in conjunction with the MC6802, to develop a basic 2-chip microcomputer system. The MC6846 consists of 2048 bytes of mask-programmable ROM, an 8-bit bidirectional data port with control lines, and a 16-bit programmable timer-counter.



This device is capable of interfacing with the MC6802 (basic MC6800, clock and 128 bytes of RAM) as well as the MC6800 if desired. No external logic is required to interface with most peripheral devices.

- 2048 8-Bit Bytes of Mask-Programmable ROM
- 8-Bit Bidirectional Data Port for Parallel Interface plus Two Control Lines
- Programmable Interval Timer-Counter Functions
- Programmable I/O Peripheral Data, Control and Direction Registers
- Compatible with the Complete M6800 Microcomputer Product Family
- TTL-Compatible Data and Peripheral Lines
- Single 5-Volt Power Supply

MC6845

CRT CONTROLLER (CRTC)

The MC6845 CRT Controller performs the interface to raster scan CRT displays. It is intended for use in processor-based controllers for CRT terminals in stand-alone or cluster configurations.

The CRTC is optimized for hardware/software balance in order to achieve integration of all key functions and maintain flexibility. For instance, all keyboard functions, R/W, cursor movements, and editing are under processor control; whereas the CRTC provides video timing and Refresh Memory Addressing.

- Applications include "glass-teletype," smart, programmable, intelligent CRT terminals; video games; information display.
- Alphanumeric, semi-graphic, and full graphic capability.
- Fully programmable via processor data bus. Can generate timing for almost any alphanumeric screen density, e.g. 80 x 24, 72 x 64, 132 x 20, etc.
- Single +5 volt supply. TTL/6800 compatible I/O.
- Hardware scroll (paging or by line or by character)
- Compatible with CPU's and MPU's which provide a means for synchronizing external devices.
- Cursor register and compare circuitry.
- Cursor format and blink are programmable.
- Light pen register.
- Line buffer-less operation. No external DMA required. Refresh Memory is multiplexed between CRTC and MPU.
- Programmable interlace or non-interlace scan.
- 14-bit wide refresh address.

MC6844

DIRECT MEMORY ACCESS CONTROLLER (DMAC)

The MC6844 Direct Memory Access Controller (DMAC) performs the function of transferring data directly between memory and peripheral device controllers. It controls the address and data buses in place of the MPU in bus organized systems such as the M6800 Microprocessor System.

The bus interface of the MC6844 includes select, read/write, interrupt, transfer request/grant, and bus interface logic to allow the data transfer over an 8-bit bidirectional data bus. The functional configuration of the DMAC is programmed via the data bus. The internal structure provides for control and handling of four individual channels, each of which is separately configured. Programmable control registers provide control for the transfer location and length, individual channel control and transfer mode configuration, priority of servicing, data chaining, and interrupt control. Status and control lines provide control to the peripheral controllers.

The mode of transfer for each channel can be programmed as cycle-stealing or a burst transfer mode.

Typical applications would be with the Floppy Disk Controller (FDC) and the Advanced Data Link Controller (ADLC).

- Four DMA Channels, Each Having a 16-Bit Address Register and a 16-Bit Byte Count Register
- 1 M Byte/Sec Maximum Data Transfer Rate
- Selection of Fixed or Rotating Priority Service Control
- Separate Control Bits for Each Channel
- Data Chain Function
- Address Increment or Decrement Update
- Programmable Interrupts and DMA End to Peripheral Controllers

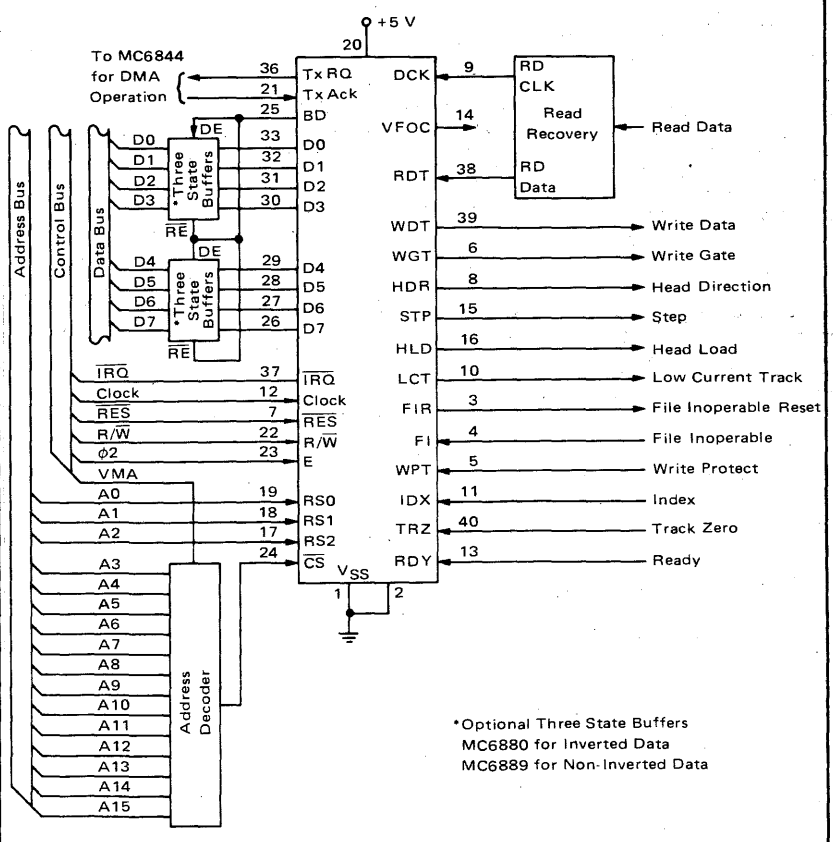
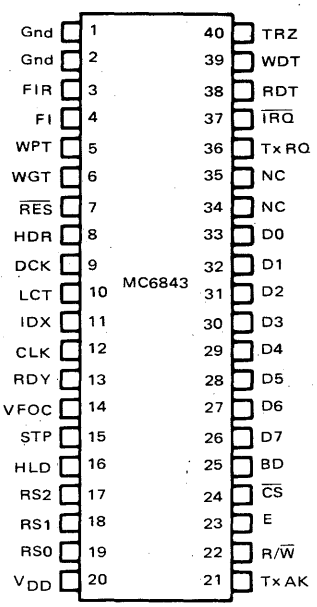
MC6843



FLOPPY DISK CONTROLLER (FDC)

The MC6843 Floppy Disk Controller performs the complex MPU/Floppy interface function. The FDC was designed to optimize the balance between the "Hardware/Software" in order to achieve integration of all key functions and maintain flexibility.

The FDC can interface a wide range of drives with a minimum of external hardware. Multiple drives can be controlled with the addition of external multiplexing rather than additional FDC's.



- Format compatible with IBM3740
- User Programmable read/write format
- Ten powerful macro commands
- Macro End Interrupt allows parallel processing of MPU and FDC
- Controls multiple Floppies with external multiplexing
- Direct interface with MC6800
- Programmable step and settling times enable operation with a wide range of Floppy drives
- Offers both Programmed Controlled I/O (PCIO) and DMA data transfer mode
- Free-Format read or write
- Single 5-volt power supply
- All registers directly accessible

MC6840

PROGRAMMABLE TIMER MODULE (PTM)

The MC6840 is a programmable subsystem component of the M6800 family designed to provide variable system time intervals.

The MC6840 has three 16-bit binary counters, three corresponding control registers and a status register. These counters are under software control and may be used to cause system interrupts and/or generate output signals. The MC6840 may be utilized for such tasks as frequency measurements, event counting, interval measuring and similar tasks. The device may be used for square wave generation, gated delay signals, single pulses of controlled duration, and pulse width modulation as well as system interrupts.

- Operates from a Single 5 Volt Power Supply
- Fully TTL Compatible
- Single System Clock Required (Enable)
- Selectable Prescaler on Timer 3 Capable of a 4 MHz Input
- Programmable Interrupts ($\overline{IRQ}$) Output to MPU
- Readable Down Counter Indicates Counts to Go to Time-Out
- Selectable Gating for Frequency or Pulse-Width Comparison
- $\overline{RESET}$ Input
- Three Asynchronous External Clock and Gate/Trigger Inputs Internally Synchronized
- Three Maskable Outputs

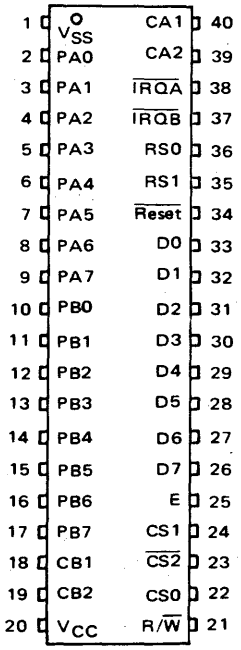
PERIPHERAL INTERFACE ADAPTER (PIA)

The MC6821 Peripheral Interface Adapter provides the universal means of interfacing peripheral equipment to the MC6800 Microprocessing Unit (MPU). This device is capable of interfacing the MPU to peripherals through two 8-bit bidirectional peripheral data buses and four control lines. No external logic is required for interfacing to most peripheral devices.



The functional configuration of the PIA is programmed by the MPU during system initialization. Each of the peripheral data lines can be programmed to act as an input or output, and each of the four control/interrupt lines may be programmed for one of several control modes. This allows a high degree of flexibility in the over-all operation of the interface.

- 8-Bit Bidirectional Data Bus for Communication with the MPU
- Two Bidirectional 8-Bit Buses for Interface to Peripherals
- Two Programmable Control Registers
- Two Programmable Data Direction Registers
- Four Individually-Controlled Interrupt Input Lines; Two Usable as Peripheral Control Outputs
- Handshake Control Logic for Input and Output Peripheral Operation
- High-Impedance 3-State and Direct Transistor Drive Peripheral Lines
- Program Controlled Interrupt and Interrupt Disable Capability
- CMOS Drive Capability on Side A Peripheral Lines
- Two TTL Drive Capability on All A and B Side Buffers
- TTL-Compatible
- Static Operation

MC6803
Internal-Clock

MC6803E
External-Clock

The MC6803 is an 8-bit microcomputer which employs a multiplexed address and data system allowing expandability to 65K words. The MC6803 is object code compatible with the M6800 instruction set and includes improved execution times of key instructions. There are several new 16-bit and 8-bit instructions including an 8 by 8 multiply with 16-bit result. The MC6803 has 128 bytes of RAM, internal clock, UART, parallel I/O, and three function 16-bit timer all on-board. The MC6803E version is also available for use with an external clock. The MC6803 internal clock version requires only the addition of an external crystal for MCU operation. The MC6803 internal clock's divide by four circuitry allows for use of the inexpensive 3.58 MHz color burst crystal. The MC6803 MCU is fully TTL compatible and requires only one +5.0 volt power supply.

- Expanded M6800 Instruction Set
- Full Object Code Compatibility With M6800 MPU/s
- Multiplexed Address and Data
- Compatible With Existing M6800 Peripherals
- 8 x 8 Multiply With 16-bit Result
- Up to 13 Parallel I/O Lines
- 128 Bytes On-Board RAM
- On-Board RAM Retainable With V_{CC} Standby
- UART (Serial I/O) On-Board
- 16-bit Timer On-Board
- Internal Clock/Divide by Four Circuitry (MC6803)
- External Clock/Divide by One Circuitry (MC6803E)
- Full TTL Compatibility
- Full Interrupt Capability

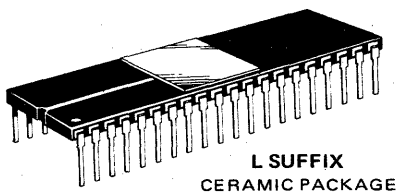
MC6802

MICROPROCESSOR WITH CLOCK AND RAM

The MC6802 is a monolithic 8-bit microprocessor that contains all the registers and accumulators of the present MC6800 plus an internal clock oscillator and driver on the same chip. In addition, the MC6802 has 128 bytes of RAM on board located at hex addresses 0000 to 007F. The first 32 bytes of RAM, at hex addresses 0000 to 001F, may be retained in a low power mode by utilizing V_{CC} standby, thus facilitating memory retention during a power-down situation.



The MC6802 is completely software compatible with the MC6800 as well as the entire M6800 family of parts. Hence, the MC6802 is expandable to 65K words.

- On-Chip Clock Circuit
- 128 x 8 Bit On-Chip RAM
- 32 Bytes of RAM Are Retainable
- Software-Compatible with the MC6800
- Expandable to 65K words
- Standard TTL-Compatible Inputs and Outputs
- 8 Bit Word Size
- 16 Bit Memory Addressing
- Interrupt Capability

ADDRESSING MODES — BOOLEAN/ARITHMETIC OPERATION — COND. CODE REG.

LEGEND:

OP Operation Code (Hexadecimal);
~ Number of MPU Cycles;
= Number of Program Bytes;
+ Arithmetic Plus;
– Arithmetic Minus;
· Boolean AND;
M_{SP} Contents of memory location pointed to be Stack Pointer;
+ Boolean Inclusive OR;
⊕ Boolean Exclusive OR;
$\overline{M}$ Complement of M;
→ Transfer Into;
0 Bit = Zero;
00 Byte = Zero;

Note – Accumulator addressing mode instructions are included in the column for IMPLIED addressing

CONDITION CODE SYMBOLS:

H Half-carry from bit 3;
I Interrupt mask
N Negative (sign bit)
Z Zero (byte)
V Overflow, 2's complement
C Carry from bit 7
R Reset Always
S Set Always
↕ Test and set if true, cleared otherwise
• Not Affected

MC3870

0° to 70°C

SINGLE-CHIP MICROCONTROLLER

The MC3870 is a complete 8-bit microcomputer on a single MOS integrated circuit. Utilizing ion-implanted, N-channel silicon-gate technology and advanced circuit design techniques, the single-chip 3870 offers maximum cost effectiveness in a wide range of control and logic replacement applications.

- Software Compatible with F8 Family
- 2048 Byte Mask Programmable ROM
- 64 Byte Scratchpad RAM
- 32 Bits (4 Ports) TTL Compatible I/O
- Programmable Binary Timer
  - Interval Timer Mode
  - Pulse Width Measurement Mode
  - Event Counter Mode
- External Interrupt
- Crystal, LC, RC, External, or Internal Time Base
- Low Power (275 mW Typ.)
- Single +5 Volt ±10% Power Supply

PIN CONNECTIONS

*Privileged Instruction
**3-Bit Octal Digit
***2 Machine Cycles for CPU Ports

NOTES

Each lowercase character represents a Hexadecimal digit.
Each cycle equals 4 machine clock periods.
Lowercase denotes variables specified by programmer.

Function Definitions

←	is replaced by
( )	the contents of
(–)	Binary "1"s complement of
+	Arithmetic Add (Binary or Decimal)
⊕	Logical OR exclusive
∧	Logical AND
∨	Logical OR inclusive
H'	Hexadecimal digit

Register Names

a	Address Variable
A	Accumulator
DC	Data Counter (Indirect Address Register)
DC_0	Data Counter #0 (Indirect Address Register #0)
DC_1	Data Counter #1 (Indirect Address Register #1)
DCL	Least significant 8 bits of Data Counter Addressed
DCU	Most significant 8 bits of Data Counter Addressed
H	Scratchpad Register #10 and #11
i and ii	Immediate Operand
ICB	Interrupt Control Bit
IS	Indirect Scratchpad Address Register
ISAR	Indirect Scratchpad Address Register
ISARL	Least significant 3 bits of ISAR
ISARU	Most significant 3 bits of ISAR
J	Scratchpad Register #9
K	Registers #12 and #13
KL	Register #13
KU	Register #12
PC_0	Program Counter
PC_0L	Least signfiicant 8 bits of Program Counter
PC_0U	Most significant 8 bits of Program Counter
PC_1	Stack Register
PC_1L	Least significant 8 bits of Program Counter
PC_1U	Most signficant 8 bits of Active Stack Register
Q	Registers #14 and #15
QL	Register #15
QU	Register #14
r	Scratchpad Register (any address through 11)
W	Status Register

Scratchpad Addressing Modes (Machine Code Format)

r C	(Hexadecimal), Register Addressed by ISAR (Unmodified)
r D	(Hexadecimal), Register Addressed by ISAR, ISARL Incremented
r E	(Hexadecimal), Register Addressed by ISAR, ISARL Decremented
r F	(No operation performed)
r O through B	(Hexadecimal), Register 0 through 11 addressed directly from the Instruction

Status Register

–	No change in condition
1/0	is set to "1" or "0" depending on conditions
CRY	Carry Flag
OVF	Overflow Flag
SIGN	Sign of Result Flag
ZERO	Zero Flag

8-BIT MICROPROCESSING UNIT (MPU)

The MC6800 is a monolithic 8-bit microprocessor forming the central control function for Motorola's M6800 family. Compatible with TTL, the MC6800, as with all M6800 system parts, requires only one +5.0-volt power supply, and no external TTL devices for bus interface.

The MC6800 is capable of addressing 65K bytes of memory with its 16-bit address lines. The 8-bit data bus is bidirectional as well as 3-state, making direct memory addressing and multiprocessing applications realizable.

- Eight-Bit Parallel Processing
- Bidirectional Data Bus
- Sixteen-Bit Address Bus – 65K Bytes of Addressing
- 72 Instructions – Variable Length
- Seven Addressing Modes – Direct, Relative, Immediate, Indexed, Extended, Implied and Accumulator
- Variable Length Stack
- Vectored Restart
- Maskable Interrupt Vector
- Separate Non-Maskable Interrupt – Internal Registers Saved in Stack
- Six Internal Registers – Two Accumulators, Index Register, Program Counter, Stack Pointer and Condition Code Register
- Direct Memory Addressing (DMA) and Multiple Processor Capability
- Simplified Clocking Characteristics
- Clock Rates as High as 2.0 MHz
- Simple Bus Interface Without TTL
- Halt and Single Instruction Execution Capability

PIN ASSIGNMENT

ORDERING INFORMATION

Speed	Device	Temperature Range
1.0 MHz	MC6800P, L	0 to 70°C
	MC6800CP, CL	-40 to +85°C
MIL-STD-883B MIL-STD-883C	MC6800BQCS MC6800CQCS	-55 to +125°C
1.5 MHz	MC68A00P, L	0 to +70°C
	MC68A00CP, CL	-40 to +85°C
2.0 MHz	MC68B00P, L	0 to +70°C

HIGH-PERFORMANCE MICROPROCESSOR

■ MC6800 COMPATIBLE

- Hardware — Interfaces With All M6800 Peripherals
- Software — Upward Compatible Instruction Set and Addressing Modes

■ HARDWARE FEATURES

- On-Chip Oscillator (MC6809)
- Optional ÷1 External Clock Inputs (MC6809E)
- MRDY Input Extends Data Access Times for Use With Slow Memory
- $\overline{BREQ}$/TSC Allows Quick Access to Bus for DMA and Memory Refresh
- Last Instruction Cycle Output for Identification of Opcode Fetch (MC6809E)
- Fast Interrupt Request Input Stacks Only Program Counter and Condition Code
- Interrupt Acknowledge Output Allows Vectoring by Device
- Busy Output Eases Multiprocessor Design (MC6809E)

■ ARCHITECTURAL FEATURES

- Two 8-Bit Accumulators Can Be Concatenated to Form One 16-Bit Accumulator
- Two 16-Bit Index Registers
- Two 16-Bit Indexable Stack Pointers
- Direct Page Register Allows Direct Addressing Throughout Memory Space

■ INSTRUCTION SET

- Extended Range Branches
- 16-Bit Arithmetic
- Push/Pull Any Register or Set of Registers To/From Either Stack
- 8 X 8 Unsigned Multiply
- Transfer/Exchange Any Two Registers of Equal Size
- Enhanced Pointer Register Manipulation

■ ADDRESSING MODES

- All MC6800 Modes, Plus PC Relative, Extended Indirect, Indexed Indirect, and PC Relative Indirect
- Direct Addressing Available for All Memory Access Instructions
- Index Mode Options Include Accumulator or Up to 16-Bit Constant Offset, and Auto-Increment/Decrement (by 1 or 2) With Any of the Four Pointer Registers

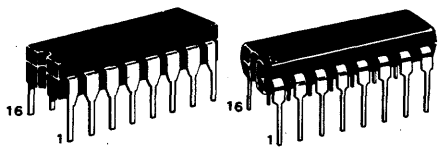
MC14500B

INDUSTRIAL CONTROL UNIT

The MC14500B Industrial Control Unit (ICU) is a single bit CMOS processor. The ICU is designed for use in systems requiring decisions based on successive single bit information. An external ROM stores the control program. With a program counter (and output latches and input multiplexers, if required) the ICU in a system forms a stored program controller that replaces combinatorial logic. Applications include relay logic processing, serial data manipulation and control. The ICU also may control an MPU or be controlled by an MPU.



- 16 Instructions
- DC to 1.0 MHz Operation at V_{DD} = 5 V
- On Chip Clock (Oscillator)
- Executes One Instruction per Clock Cycle
- 3 V to 18 V Operation
- Noise Immunity Typically 45% of V_{DD}
- Quiescent Current 5.0 μAdc Typical at V_{DD} = 5 V
- Capable of Driving One Low-Power Schottky Load or Two Low-Power TTL Loads over Full Temperature Range

Detailed operation and applications are given in the "MC14500B Industrial Control Unit" handbook.

BLOCK DIAGRAM

PIN ASSIGNMENT

MAXIMUM RATINGS (Voltages referenced to V_{SS})

Rating	Symbol	Value	Unit
DC Supply Voltage	V_{DD}	-0.5 to +18	Vdc
Input Voltage, All Inputs	V_{in}	-0.5 to V_{DD} + 0.5	Vdc
DC Current Drain per Pin	I	10	mAdc
Operating Temperature Range — AL Device CL/CP Device	T_A	-55 to +125 -40 to +85	°C
Storage Temperature Range	T_{stg}	-65 to +150	°C

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. For proper operation it is recommended that V_{in} and V_{out} be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

This is advance information and specifications are subject to change without notice.

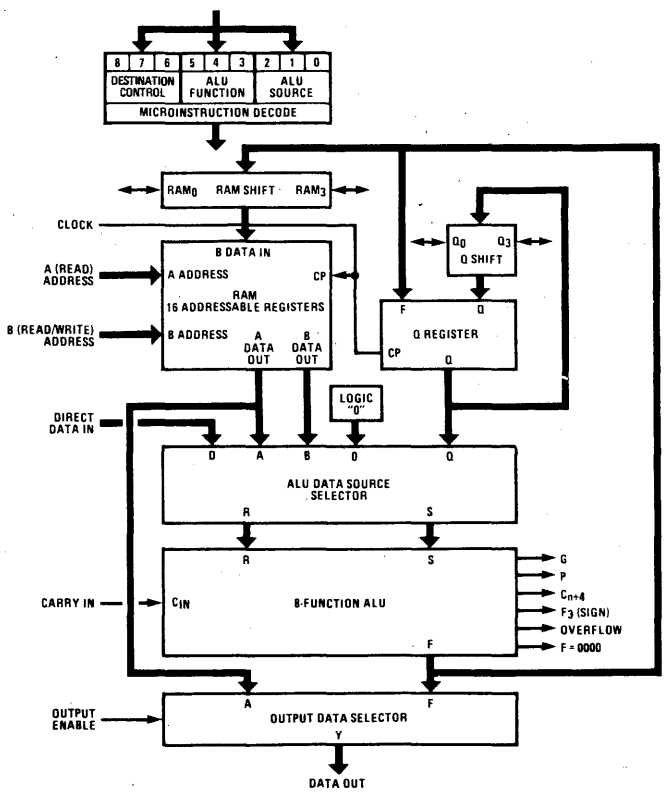
IDM2901A-1 4-Bit Bipolar Microprocessor

General Description



The IDM2901A-1 4-bit bipolar microprocessor slice is a cascadable device designed for use in Central Processing Units, programmable microprocessors, peripheral controllers, and other "high-speed" applications where economy, hardware/software flexibility, and easy expansion are system prerequisites. The building-block architecture and microinstruction format of the IDM2901A-1 permits efficient emulation of most digital-based systems.

As shown in the simplified block diagram, the IDM2901A-1 device consists of a 16-word by 4-bit 2-port RAM, a high-speed ALU, and the required shifting, decoding, and multiplexing circuits. The 9-bit microinstruction word is organized into three groups of three bits each — the first group (bits 0 - 2) selects ALU source operands, the second group (bits 3 - 5) selects the ALU function, and the last group (bits 6 - 8) selects the destination register within the ALU. The slice microprocessor is cascadable with full look-ahead or ripple carry; all outputs are TRI-STATE® and four status-flag outputs are available. To minimize power consumption and to maximize speed and reliability, the 40-pin LSI chip is fabricated using state-of-the-art (Low-Power Schottky) technology.

Features and Benefits

- **Multiple-address architecture** — improves system speed by providing simultaneous yet independent access to two working registers.
- **Multifunction ALU** — performs addition, two subtraction operations, and five logic functions on two source operands.
- **Flexible data-source selection** — for every ALU function, data is selected from five source ports for a total of 203 source operand pairs.
- **Left/right shift independent of ALU** — an arithmetic operation and a left or right shift can be obtained on the same machine cycle.
- **Four status flags** — carry, overflow, zero, and functional sign are available as outputs.
- **Expandable** — Connect any number of IDM2901A-1s together for longer word lengths.
- **Microprogrammable** — three groups of 3 bits each for source operand, ALU function, and destination control.

Guaranteed Operating Conditions Over Temperature and Voltage

When operated in a system, the timing requirements for the IDM2901A-1 are defined in tables 1, 2, and 3. Table 1 provides clock characteristics of the IDM2901A-1, table 2 gives the combinational delay times from input to output, and table 3 specifies setup and hold times. If used according to the specified delay and setup times, the device is guaranteed to function properly over the entire operating range. Table 3 defines the time prior to the end of the cycle (low-to-high transition of clock pulse) that each input must be stable to guarantee that the correct data is written into one of the internal registers.

Table 1. Cycle Time and Clock Characteristics

Time	IDM2901A-1	
	DC, NC	DM, DM/883
Read-Modify-Write Cycle (time from selection of A, B registers to end of cycle)	60 ns	75 ns
Maximum Clock Frequency to Shift Q Register (50% duty cycle)	16 MHz	16 MHz
Minimum Clock Low Time	25 ns	30 ns
Minimum Clock High Time	25 ns	30 ns
Minimum Clock Period	60 ns	75 ns

Table 2. Maximum Combinational Propagation Delays (all in ns; $C_L \leq 50$ pF)

Table 3. Maximum Setup and Hold Times (all in ns) — Note 1

		Commercial IDM2901A-1 DC, NC (0°C to +70°C, 5V ± 5%)		Military IDM2901A-1 DM, DM/883 (−55°C to +125°C, 5V ± 10%)	
From Input	Notes	Setup Time	Hold Time	Setup Time	Hold Time
A, B Source	2, 3, 4, 5	60, $t_{pw}L$ + 20	0	75, $t_{pw}L$ + 25	0
B Destination	2, 4	$t_{pw}L$ + 15	0	$t_{pw}L$ + 15	0
D (arithmetic mode)		40	0	50	0
D (I = X37)	5	40	0	50	0
C_n		35	0	40	0
$I_{2,1,0}$		45	0	55	0
$I_{5,4,3}$		45	0	55	0
$I_{8,7,6}$	4	$t_{pw}L$ + 15	0	$t_{pw}L$ + 15	0
$RAM_{0,3}/Q_{0,3}$		15/10	0	25/15	0

Note 1: See figures 9 and 10.

Note 2: If the B address is used as a source operand, allow for the "A, B Source" setup time; if it is used only for the destination address, use the "B Destination" setup time.

Note 3: Where two numbers are shown, both must be met.

Note 4: "$t_{pw}L$" is the clock low time.

Note 5: DVO is the fastest way to load the RAM from the D inputs. This function is obtained with I = X37.

Note 6: Using Q register as source operand in arithmetic mode. Clock is not normally in critical speed path when Q is not a source.

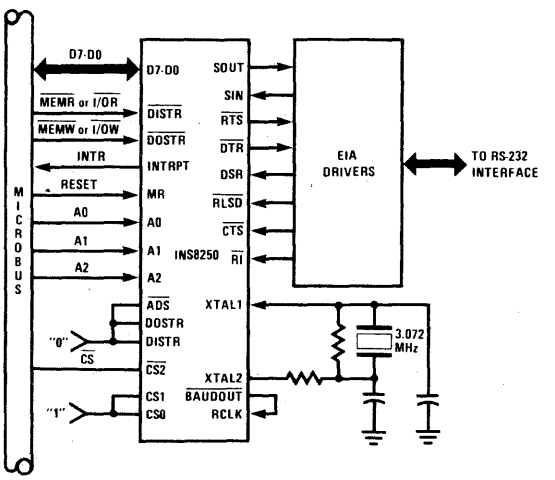
INS8250 Asynchronous Communications Element

General Description

The INS8250 is a programmable Asynchronous Communications Element (ACE) chip contained in a standard 40-pin dual-in-line package. The chip, which is fabricated using N-channel silicon gate technology, functions as a serial data input/output interface in a microcomputer system. The functional configuration of the INS8250 is programmed by the system software via a TRI-STATE® 8-bit bidirectional data bus.



The INS8250 performs serial-to-parallel conversion on data characters received from a peripheral device or a MODEM, and parallel-to-serial conversion on data characters received from the CPU. The CPU can read the complete status of the INS8250 at any time during the functional operation. Status information reported includes the type and condition of the transfer operations being performed by the INS8250, as well as any error conditions (parity, overrun, framing, or break interrupt).

In addition to providing control of asynchronous data communications, the INS8250 includes a programmable Baud Generator that is capable of dividing the timing reference clock input by divisors of 1 to $(2^{16} - 1)$, and producing a 16x clock for driving the internal transmitter logic. Provisions are also included to use this 16x clock to drive the receiver logic. Also included in the INS8250 is a complete MODEM-control capability, and a processor-interrupt system that may be software tailored to the user's requirements to minimize the computing time required to handle the communications link.

Features

- Designed to be Easily Interfaced to Most Popular Microprocessors.
- Adds or Deletes Standard Asynchronous Communication Bits (Start, Stop, and Parity) to or from Serial Data Stream
- Full Double Buffering Eliminates Need for Precise Synchronization
- Independently Controlled Transmit, Receive, Line Status, and Data Set Interrupts
- Programmable Baud Rate Generator Allows Division of Any Input Clock by 1 to $(2^{16} - 1)$ and Generates the Internal 16x Clock
- Independent Receiver Clock Input
- MODEM Control Functions (CTS, RTS, DSR, DTR, RI, and Carrier Detect)
- Fully Programmable Serial-Interface Characteristics
  - 5-, 6-, 7-, or 8-Bit Characters
  - Even, Odd, or No-Parity Bit Generation and Detection
  - 1-, 1½-, or 2-Stop Bit Generation
  - Baud Rate Generation (DC to 56k Baud)
- False Start Bit Detection
- Complete Status Reporting Capabilities
- TRI-STATE TTL Drive Capabilities for Bidirectional Data Bus and Control Bus
- Line Break Generation and Detection
- Internal Diagnostic Capabilities
  - Loopback Controls for Communications Link Fault Isolation
  - Break, Parity, Overrun, Framing Error Simulation
- Full Prioritized Interrupt System Controls
- Single +5-Volt Power Supply
- MICROBUS™* Compatible

INS8250 MICROBUS Configuration

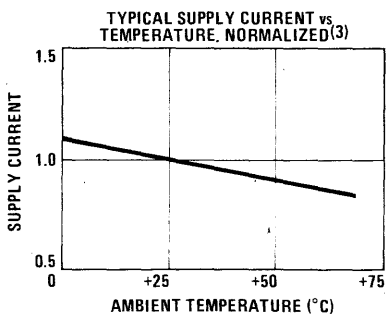
Absolute Maximum Ratings

Temperature Under Bias . . . . . 0°C to +70°C
Storage Temperature . . . . . −65°C to +150°C
All Input or Output Voltages with Respect to V_{SS} . . . . −0.5 V to +7.0 V
Power Dissipation . . . . . 400 mW

Absolute maximum ratings indicate limits beyond which permanent damage may occur. Continuous operation at these limits is not intended; operation should be limited to those conditions specified under DC Electrical Characteristics.

DC Electrical Characteristics



T_A = 0°C to +70°C, V_{CC} = +5 V ± 5%, V_{SS} = 0 V, unless otherwise specified.

Symbol	Parameter	Min	Typ	Max	Units	Test Conditions
V_{ILX}	Clock Input Low Voltage	−0.5		0.8	V	
V_{IHX}	Clock Input High Voltage	2.0		V_{CC}	V	
V_{IL}	Input Low Voltage	−0.5		0.8	V	
V_{IH}	Input High Voltage	2.0		V_{CC}	V	
V_{OL}	Output Low Voltage			0.4	V	I_{OL} = 1.6 mA on all outputs,
V_{OH}	Output High Voltage	2.4			V	I_{OH} = −100 μA
I_{CC} (AV)	Avg Power Supply Current (V_{CC})		65	80	mA	
I_{IL}	Input Leakage			±10	μA	
I_{CL}	Clock Leakage			±10	μA	

Capacitance

T_A = 25°C, V_{CC} = V_{SS} = 0 V

Symbol	Parameter	Min	Typ	Max	Units	Test Conditions
C_{XIN}	Clock Input Capacitance		15	20	pF	
C_{XOUT}	Clock Output Capacitance		20	30	pF	f_C = 1 MHz
C_{IN}	Input Capacitance		6	10	pF	Unmeasured pins returned to V_{SS}
C_{OUT}	Output Capacitance		10	20	pF	

©IC MASTER 1979

INS8250 Block Diagram

INS8250 Functional Pin Description

The following describes the function of all INS8250 input/output pins. Some of these descriptions reference internal circuits.

NOTE

In the following descriptions, a low represents a logic 0 (0 volt nominal) and a high represents a logic 1 (+2.4 volts nominal).

INPUT SIGNALS

Chip Select (CS0, CS1, $\overline{CS2}$), Pins 12 - 14: When CS0 and CS1 are high and $\overline{CS2}$ is low, the chip is selected. Chip selection is complete when the decoded chip select signal is latched with an active (low) Address Strobe ($\overline{ADS}$) input. This enables communication between the INS8250 and the CPU.

Data Input Strobe (DISTR, $\overline{DISTR}$), Pins 22 and 21: When DISTR is high or $\overline{DISTR}$ is low while the chip is selected, allows the CPU to read status information or data from a selected register of the INS8250.

NOTE

Only an active DISTR or $\overline{DISTR}$ input is required to transfer data from the INS8250 during a read operation. Therefore, tie either the DISTR input permanently low or the $\overline{DISTR}$ input permanently high, if not used.

Data Output Strobe (DOSTR, $\overline{DOSTR}$), Pins 19 and 18: When DOSTR is high or $\overline{DOSTR}$ is low while the chip is selected, allows the CPU to write data or control words into a selected register of the INS8250.

NOTE

Only an active DOSTR or $\overline{DOSTR}$ input is required to transfer data to the INS8250 during a write operation. Therefore, tie either the DOSTR input permanently low or the $\overline{DOSTR}$ input permanently high, if not used.

Address Strobe ($\overline{ADS}$), Pin 25: When low, provides latching for the Register Select (A0, A1, A2) and Chip Select (CS0, CS1, $\overline{CS2}$) signals.

NOTE

An active $\overline{ADS}$ input is required when the Register Select (A0, A1, A2) signals are not stable for the duration of a read or write operation. If not required, tie the $\overline{ADS}$ input permanently low.

Register Select (A0, A1, A2), Pins 26 - 28: These three inputs are used during a read or write operation to select an INS8250 register to read from or write into as indicated in the table below. Note that the state of the Divisor Latch Access Bit (DLAB), which is the most significant bit of the Line Control Register, affects the selection of certain INS8250 registers. The DLAB must be set high by the system software to access the Baud Generator Divisor Latches.

©IC MASTER 1979

DLAB	A_2	A_1	A_0	Register
0	0	0	0	Receiver Buffer (read), Transmitter Holding Register (write)
0	0	0	1	Interrupt Enable
X	0	1	0	Interrupt Identification (read only)
X	0	1	1	Line Control
X	1	0	0	MODEM Control
X	1	0	1	Line Status
X	1	1	0	MODEM Status
X	1	1	1	None
1	0	0	0	Divisor Latch (least significant byte)
1	0	0	1	Divisor Latch (most significant byte)

Master Reset (MR), Pin 35: When high, clears all the registers (except the Receiver Buffer, Transmitter Holding, and Divisor Latches), and the control logic of the INS8250. Also, the state of various output signals (SOUT, INTRPT, $\overline{OUT\,1}$, $\overline{OUT\,2}$, $\overline{RTS}$, $\overline{DTR}$) are affected by an active MR input. (Refer to table 1.)

Receiver Clock (RCLK), Pin 9: This input is the 16x baud rate clock for the receiver section of the chip.

Serial Input (SIN), Pin 10: Serial data input from the communications link (peripheral device, MODEM, or data set).

Clear to Send ($\overline{CTS}$), Pin 36: The $\overline{CTS}$ signal is a MODEM control function input whose condition can be tested by the CPU by reading bit 4 (CTS) of the MODEM Status Register. Bit 0 (DCTS) of the MODEM Status Register indicates whether the $\overline{CTS}$ input has changed state since the previous reading of the MODEM Status Register.

NOTE

Whenever the CTS bit of the MODEM Status Register changes state, an interrupt is generated if the MODEM Status Interrupt is enabled.

Data Set Ready ($\overline{DSR}$), Pin 37: When low, indicates that the MODEM or data set is ready to establish the communications link and transfer data with the INS8250. The $\overline{DSR}$ signal is a MODEM-control function input whose condition can be tested by the CPU by reading bit 5 (DSR) of the MODEM Status Register. Bit 1 (DDSR) of the MODEM Status Register indicates whether the $\overline{DSR}$ input has changed state since the previous reading of the MODEM Status Register.

NOTE

Whenever the DSR bit of the MODEM Status Register changes state, an interrupt is generated if the MODEM Status Interrupt is enabled.

Received Line Signal Detect ($\overline{RLSD}$), Pin 38: When low, indicates that the data carrier has been detected by the MODEM or data set. The $\overline{RLSD}$ signal is a MODEM-control function input whose condition can be tested by the CPU by reading bit 7 (RLSD) of the MODEM Status Register. Bit 3 (DRLSD) of the MODEM Status Register indicates whether the $\overline{RLSD}$ input has changed state since the previous reading of the MODEM Status Register.

NOTE

Whenever the RLSD bit of the MODEM Status Register changes state, an interrupt is generated if the MODEM Status Interrupt is enabled.

Ring Indicator ($\overline{RI}$), Pin 39: When low, indicates that a telephone ringing signal has been received by the MODEM or data set. The $\overline{RI}$ signal is a MODEM-control function input whose condition can be tested by the CPU by reading bit 6 (RI) of the MODEM Status Register. Bit 2 (TERI) of the MODEM Status Register indicates whether the $\overline{RI}$ input has changed from a low to a high state since the previous reading of the MODEM Status Register.

NOTE

Whenever the RI bit of the MODEM Status Register changes from a high to a low state, an interrupt is generated if the MODEM Status Interrupt is enabled.

V_{CC}, Pin 40: +5-volt supply.

V_{SS}, Pin 20: Ground (0-volt) reference.

OUTPUT SIGNALS

Data Terminal Ready ($\overline{DTR}$), Pin 33: When low, informs the MODEM or data set that the INS8250 is ready to communicate. The DTR output signal can be set to an active low by programming bit 0 (DTR) of the MODEM Control Register to a high level. The $\overline{DTR}$ signal is set high upon a Master Reset operation.

Request to Send ($\overline{RTS}$), Pin 32: When low, informs the MODEM or data set that the INS8250 is ready to transmit data. The $\overline{RTS}$ output signal can be set to an active low by programming bit 1 (RTS) of the MODEM Control Register. The $\overline{RTS}$ signal is set high upon a Master Reset operation.

Output 1 ($\overline{OUT\,1}$), Pin 34: User-designated output that can be set to an active low by programming bit 2 ($\overline{OUT\,1}$) of the MODEM Control Register to a high level. The $\overline{OUT\,1}$ signal is set high upon a Master Reset operation.

Output 2 ($\overline{OUT\,2}$), Pin 31: User-designated output that can be set to an active low by programming bit 3 ($\overline{OUT\,2}$) of the MODEM Control Register to a high level. The $\overline{OUT\,2}$ signal is set high upon a Master Reset operation.

Chip Select Out (CSOUT), Pin 24: When high, indicates that the chip has been selected by active CS0, CS1, and $\overline{CS2}$ inputs. No data transfer can be initiated until the CSOUT signal is a logic 1.

Driver Disable (DDIS), Pin 23: Goes low whenever the CPU is reading data from the INS8250. A high-level DDIS output can be used to disable an external transceiver (if used between the CPU and INS8250 on the $D_7 - D_0$ Data Bus) at all times, except when the CPU is reading data.

Baud Out ($\overline{BAUDOUT}$), Pin 15: 16x clock signal for the transmitter section of the INS8250. The clock rate is equal to the main reference oscillator frequency divided by the specified divisor in the Baud Generator Divisor Latches. The $\overline{BAUDOUT}$ may also be used for the receiver section by tying this output to the RCLK input of the chip.

Interrupt (INTRPT), Pin 30: Goes high whenever any one of the following interrupt types has an active high condition and is enabled via the IER: Receiver Error Flag; Received Data Available; Transmitter Holding Register Empty; and MODEM Status. The INTRPT signal is reset low upon the appropriate interrupt service or a Master Reset operation.

©IC MASTER 1979

Serial Output (SOUT), Pin 11: Composite serial data output to the communications link (peripheral, MODEM or data set). The SOUT signal is set to the Marking (logic 1) state upon a Master Reset operation.

INPUT/OUTPUT SIGNALS

Data (D_7 - D_0) Bus, Pins 1 - 8: This bus comprises eight TRI-STATE input/output lines. The bus provides bidirectional communications between the INS8250 and the CPU. Data, control words, and status information are transferred via the D_7 - D_0 Data Bus.

External Clock Input/Output (XTAL 1, XTAL 2), Pins 16 and 17: These two pins connect the main timing reference (crystal or signal clock) to the INS8250.

Pin Configuration

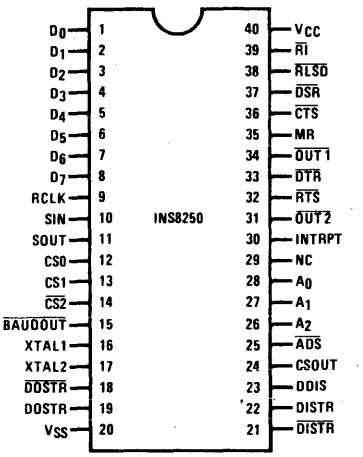

Table 1. ACE Reset Functions

Register/Signal	Reset Control	Reset State
Interrupt Enable Register	Master Reset	All Bits Low (0 - 3 forced and 4 - 7 permanent)
Interrupt Identification Register	Master Reset	Bit 0 is High, Bits 1 and 2 Low Bits 3 - 7 are Permanently Low
Line Control Register	Master Reset	All Bits Low
MODEM Control Register	Master Reset	All Bits Low
Line Status Register	Master Reset	All Bits Low, Except Bits 5 & 6 are High
MODEM Status Register	Master Reset	Bits 0 - 3 Low Bits 4 - 7 — Input Signal
SOUT	Master Reset	High
INTRPT (RCVR Errs)	Read LSR/MR	Low
INTRPT (RCVR Data Ready)	Read RBR/MR	Low
INTRPT (THRE)	Read IIR/Write THR/MR	Low
INTRPT (Modem Status Changes)	Read MSR/MR	Low
$\overline{\text{OUT 2}}$	Master Reset	High
$\overline{\text{RTS}}$	Master Reset	High
$\overline{\text{DTR}}$	Master Reset	High
$\overline{\text{OUT 1}}$	Master Reset	High

INS8250 Accessible Registers

The system programmer may access or control any of the INS8250 registers summarized in table 2 via the CPU. These registers are used to control INS8250 operations and to transmit and receive data.

INS8250 LINE CONTROL REGISTER

The system programmer specifies the format of the asynchronous data communications exchange via the Line Control Register. In addition to controlling the format, the programmer may retrieve the contents of the Line Control Register for inspection. This feature simplifies system programming and eliminates the need for separate storage in system memory of the line characteristics. The contents of the Line Control Register are indicated in table 2 and are described below.

Bits 0 and 1: These two bits specify the number of bits in each transmitted or received serial character. The encoding of bits 0 and 1 is as follows:

Bit 1	Bit 0	Word Length
0	0	5 Bits
0	1	6 Bits
1	0	7 Bits
1	1	8 Bits

Bit 2: This bit specifies the number of Stop bits in each transmitted or received serial character. If bit 2 is a logic 0, 1 Stop bit is generated or checked in the transmit or receive data, respectively. If bit 2 is a logic 1 when a 5-bit word length is selected via bits 0 and 1, 1½ Stop bits are generated or checked. If bit 2 is a logic 1 when either a 6-, 7-, or 8-bit word length is selected, 2 Stop bits are generated or checked.

Table 2. Summary of INS8250 Accessible Registers

	Register Address									
	0 DLAB = 0	0 DLAB = 0	1 DLAB = 0	2	3	4	5	6	0 DLAB = 1	1 DLAB = 1
Bit No.	Receiver Buffer Register (Read Only)	Transmitter Holding Register (Write Only)	Interrupt Enable Register	Interrupt Identification Register (Read Only)	Line Control Register	MODEM Control Register	Line Status Register	MODEM Status Register	Divisor Latch (LS)	Divisor Latch (MS)
	RBR	THR	IER	IIR	LCR	MCR	LSR	MSR	DLL	DLM
0	Data Bit 0*	Data Bit 0	Enable Received Data Available Interrupt (ERBFI)	"0" if Interrupt Pending	Word Length Select Bit 0 (WLS0)	Data Terminal Ready (DTR)	Data Ready (DR)	Delta Clear to Send (DCTS)	Bit 0	Bit 8
1	Data Bit 1	Data Bit 1	Enable Transmitter Holding Register Empty Interrupt (ETBEI)	Interrupt ID Bit (0)	Word Length Select Bit 1 (WLS1)	Request to Send (RTS)	Overrun Error (OR)	Delta Data Set Ready (DDSR)	Bit 1	Bit 9
2	Data Bit 2	Data Bit 2	Enable Receiver Line Status Interrupt (ELSI)	Interrupt ID Bit (1)	Number of Stop Bits (STB)	Out 1	Parity Error (PE)	Trailing Edge Ring Indicator (TERI)	Bit 2	Bit 10
3	Data Bit 3	Data Bit 3	Enable MODEM Status Interrupt (EDSSI)	0	Parity Enable (PEN)	Out 2	Framing Error (FE)	Delta Receive Line Signal Detect (DRLSD)	Bit 3	Bit 11
4	Data Bit 4	Data Bit 4	0	0	Even Parity Select (EPS)	Loop	Break Interrupt (BI)	Clear to Send (CTS)	Bit 4	Bit 12
5	Data Bit 5	Data Bit 5	0	0	Stick Parity	0	Transmitter Holding Register Empty (THRE)	Data Set Ready (DSR)	Bit 5	Bit 13
6	Data Bit 6	Data Bit 6	0	0	Set Break	0	Transmitter Shift Register Empty (TSRE)	Ring Indicator (RI)	Bit 6	Bit 14
7	Data Bit 7	Data Bit 7	0	0	Divisor Latch Access Bit (DLAB)	0	0	Received Line Signal Detect (RLSD)	Bit 7	Bit 15

* Bit 0 is the least significant bit. It is the first bit serially transmitted or received.

©IC MASTER 1979

Bit 3: This bit is the Parity Enable bit. When bit 3 is a logic 1, a Parity bit is generated (transmit data) or checked (receive data) between the last data word bit and Stop bit of the serial data. (The Parity bit is used to produce an even or odd number of 1s when the data word bits and the Parity bit are summed.)

Bit 4: This bit is the Even Parity Select bit. When bit 3 is a logic 1 and bit 4 is a logic 0, an odd number of logic 1s is transmitted or checked in the data word bits and Parity bit. When bit 3 is a logic 1 and bit 4 is a logic 1, an even number of bits is transmitted or checked.

Bit 5: This bit is the Stick Parity bit. When bit 3 is a logic 1 and bit 5 is a logic 1, the Parity bit is transmitted and then detected by the receiver as a logic 0 if bit 4 is a logic 1 or as a logic 1 if bit 4 is a logic 0.

Bit 6: This bit is the Set Break Control bit. When bit 6 is a logic 1, the serial output (SOUT) is forced to the Spacing (logic 0) state and remains there regardless of other transmitter activity. The set break is disabled by setting bit 6 to a logic 0. This feature enables the CPU to alert a terminal in a computer communications system.

Bit 7: This bit is the Divisor Latch Access Bit (DLAB). It must be set high (logic 1) to access the Divisor Latches of the Baud Rate Generator during a Read or Write operation. It must be set low (logic 0) to access the Receiver Buffer, the Transmitter Holding Register, or the Interrupt Enable Register.

INS8250 PROGRAMMABLE BAUD RATE GENERATOR

The INS8250 contains a programmable Baud Rate Generator that is capable of taking any clock input (DC to 3.1 MHz) and dividing it by any divisor from 1 to $(2^{16}-1)$. The output frequency of the Baud Generator is 16x the Baud rate [divisor # = (frequency input) ÷ (baud rate x 16)]. Two 8-bit latches store the divisor in a 16-bit binary format. These Divisor Latches must be loaded during initialization in order to insure desired operation of the Baud Rate Generator. Upon loading either of the Divisor Latches, a 16-bit Baud counter is immediately loaded. This prevents long counts on initial load.

Tables 3 and 4 illustrate the use of the Baud Rate Generator with crystal frequencies of 1.8432 MHz and 3.072 MHz respectively. For baud rates of 38400 and below the error obtained is minimal. The accuracy of the desired baud rate is dependent on the crystal frequency chosen.

NOTE

The maximum operating frequency of the Baud Generator is 3.1 MHz. However, when using divisors of 3 and below, the maximum frequency is equal to the divisor in MHz. For example, if the divisor is 1, then the maximum frequency is 1 MHz. In no case should the data rate be greater than 56k Baud.

LINE STATUS REGISTER

This 8-bit register provides status information to the CPU concerning the data transfer. The contents of the Line Status Register are indicated in table 2 and are described below.

Bit 0: This bit is the receiver Data Ready (DR) indicator. Bit 0 is set to a logic 1 whenever a complete incoming character has been received and transferred into the Receiver Buffer Register. Bit 0 may be reset to a logic 0 either by the CPU reading the data in the Receiver Buffer Register or by writing a logic 0 into it from the CPU.

Bit 1: This bit is the Overrun Error (OE) indicator. Bit 1 indicates that data in the Receiver Buffer Register was not read by the CPU before the next character was transferred into the Receiver Buffer Register, thereby destroying the previous character. The OE indicator is reset whenever the CPU reads the contents of the Line Status Register.

Bit 2: This bit is the Parity Error (PE) indicator. Bit 2 indicates that the received data character does not have the correct even or odd parity, as selected by the even-parity-select bit. The PE bit is set to a logic 1 upon detection of a parity error and is reset to a logic 0 whenever the CPU reads the contents of the Line Status Register.

Table 3. Baud Rates Using 1.8432 MHz Crystal

Desired Baud Rate	Divisor Used to Generate 16x Clock	Percent Error Difference Between Desired & Actual
50	2304	–

©IC MASTER 1979

Bit 3: This bit is the Framing Error (FE) indicator. Bit 3 indicates that the received character did not have a valid Stop bit. Bit 3 is set to a logic 1 whenever the Stop bit following the last data bit or parity bit is detected as a zero bit (Spacing level).

Bit 4: This bit is the Break Interrupt (BI) indicator. Bit 4 is set to a logic 1 whenever the received data input is held in the Spacing (logic 0) state for longer than a full word transmission time (that is, the total time of Start bit + data bits + Parity + Stop bits).

NOTE

Bits 1 through 4 are the error conditions that produce a Receiver Line Status interrupt whenever any of the corresponding conditions are detected.

Bit 5: This bit is the Transmitter Holding Register Empty (THRE) indicator. Bit 5 indicates that the INS8250 is ready to accept a new character for transmission. In addition, this bit causes the INS8250 to issue an interrupt to the CPU when the Transmit Holding Register Empty Interrupt enable is set high. The THRE bit is set to a logic 1 when a character is transferred from the Transmitter Holding Register into the Transmitter Shift Register. The bit is reset to logic 0 concurrently with the loading of the Transmitter Holding Register by the CPU.

Bit 6: This bit is the Transmitter Shift Register Empty (TSRE) indicator. Bit 6 is set to a logic 1 whenever the Transmitter Shift Register is idle. It is reset to logic 0 upon a data transfer from the Transmitter Holding Register to the Transmitter Shift Register. Bit 6 is a read-only bit.

Bit 7: This bit is permanently set to logic 0.

INTERRUPT IDENTIFICATION REGISTER

The INS8250 has an on-chip interrupt capability that allows for complete flexibility in interfacing to all the popular microprocessors presently available. In order to provide minimum software overhead during data character transfers, the INS8250 prioritizes interrupts into four levels. The four levels of interrupt conditions are as follows: Receiver Line Status (priority 1); Received Data Ready (priority 2); Transmitter Holding Register Empty (priority 3); and MODEM Status (priority 4).

Information indicating that a prioritized interrupt is pending and the type of that interrupt are stored in the Interrupt Identification Register (refer to table 5). The Interrupt Identification Register (IIR), when addressed during chip-select time, freezes the highest priority interrupt pending and no other interrupts are acknowledged until the particular interrupt is serviced by the CPU. The contents of the IIR are indicated in table 2 and are described below.

Bit 0: This bit can be used in either a hardwired prioritized or polled environment to indicate whether an interrupt is pending. When bit 0 is a logic 0, an interrupt is pending and the IIR contents may be used as a pointer to the appropriate interrupt service routine. When bit 0 is a logic 1, no interrupt is pending and polling (if used) continues.

Bits 1 and 2: These two bits of the IIR are used to identify the highest priority interrupt pending as indicated in table 5.

Bits 3 through 7: These five bits of the IIR are always logic 0.

Table 5. Interrupt Control Functions

Interrupt Identification Register			Interrupt Set and Reset Functions			
Bit 2	Bit 1	Bit 0	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Control
0	0	1	—	None	None	—
1	1	0	Highest	Receiver Line Status	Overrun Error or Parity Error or Framing Error or Break Interrupt	Reading the Line Status Register
1	0	0	Second	Received Data Available	Receiver Data Available	Reading the Receiver Buffer Register
0	1	0	Third	Transmitter Holding Register Empty	Transmitter Holding Register Empty	Reading the IIR Register (if source of interrupt) or Writing into the Transmitter Holding Register
0	0	0	Fourth	MODEM Status	Clear to Send or Data Set Ready or Ring Indicator or Received Line Signal Detect	Reading the MODEM Status Register

©IC MASTER 1979

INTERRUPT ENABLE REGISTER

This 8-bit register enables the four types of interrupts of the INS8250 to separately active the chip Interrupt (INTRPT) output signal. It is possible to totally disable the interrupt system by resetting bits 0 through 3 of the Interrupt Enable Register. Similarly, by setting the appropriate bits of this register to a logic 1, selected interrupts can be enabled. Disabling the interrupt system inhibits the Interrupt Identification Register and the active (high) INTRPT output from the chip. All other system functions operate in their normal manner, including the setting of the Line Status and MODEM Status Registers. The contents of the Interrupt Enable Register are indicated in table 2 and are described below.

Bit 0: This bit enables the Received Data Available Interrupt when set to logic 1.

Bit 1: This bit enables the Transmitter Holding Register Empty Interrupt when set to logic 1.

Bit 2: This bit enables the Receiver Line Status Interrupt when set to logic 1.

Bit 3: This bit enables the MODEM Status Interrupt when set to logic 1.

Bits 4 through 7: These four bits are always logic 0.

MODEM CONTROL REGISTER

This 8-bit register controls the interface with the MODEM or data set (or a peripheral device emulating a MODEM). The contents of the MODEM Control Register are indicated in table 2 and are described below.

Bit 0: This bit controls the Data Terminal Ready ($\overline{DTR}$) output. When bit 0 is set to a logic 1, the $\overline{DTR}$ output is forced to a logic 0. When bit 0 is reset to a logic 0, the $\overline{DTR}$ output is forced to a logic 1.

NOTE

The $\overline{DTR}$ output of the INS8250 may be applied to an EIA inverting line driver (such as the DS1488) to obtain the proper polarity input at the succeeding MODEM or data set.

Bit 1: This bit controls the Request to Send ($\overline{RTS}$) output. Bit 1 affects the $\overline{RTS}$ output in a manner identical to that described above for bit 0.

Bit 2: This bit controls the Output 1 ($\overline{OUT\ 1}$) signal, which is an auxiliary user-designated output. Bit 2 affects the $\overline{OUT\ 1}$ output in a manner identical to that described above for bit 0.

Bit 3: This bit controls the Output 2 ($\overline{OUT\ 2}$) signal, which is an auxiliary user-designated output. Bit 3 affects the $\overline{OUT\ 2}$ output in a manner identical to that described above for bit 0.

Bit 4: This bit provides a loopback feature for diagnostic testing of the INS8250. When bit 4 is set to logic 1, the following occur: the transmitter Serial Output (SOUT) is set to the Marking (logic 1) state; the receiver Serial Input (SIN) is disconnected; the output of the Transmitter Shift Register is "looped back" into the Receiver Shift Register input; the four MODEM Control inputs ($\overline{CTS}$, $\overline{DSR}$, $\overline{RLSD}$, and $\overline{RI}$) are disconnected; and the four MODEM Control outputs ($\overline{DTR}$, $\overline{RTS}$, $\overline{OUT\ 1}$, and $\overline{OUT\ 2}$) are internally connected to the four MODEM Control inputs. In the diagnostic mode, data that is transmitted is immediately received. This feature allows the processor to verify the transmit- and receive-data paths of the INS8250.

In the diagnostic mode, the receiver and transmitter interrupts are fully operational. The MODEM Control Interrupts are also operational but the interrupts' sources are now the lower four bits of the MODEM Control Register instead of the four MODEM Control inputs. The interrupts are still controlled by the Interrupt Enable Register.

The INS8250 interrupt system can be tested by writing into the lower six bits of the Line Status Register and the lower four bits of the MODEM Status Register. Setting any of these bits to a logic 1 generates the appropriate interrupt (if enabled). The resetting of these interrupts is the same as in normal INS8250 operation. To return to normal operation, the registers must be reprogrammed for normal operation and then bit 4 of the MODEM Control Register must be reset to logic 0.

Bits 5 through 7: These bits are permanently set to logic 0.

MODEM STATUS REGISTER

This 8-bit register provides the current state of the control lines from the MODEM (or peripheral device) to the CPU. In addition to this current-state information, four bits of the MODEM Status Register provide change information. These bits are set to a logic 1 whenever a control input from the MODEM changes state. They are reset to logic 0 whenever the CPU reads the MODEM Status Register.

The contents of the MODEM Status Register are indicated in table 2 and are described below.

Bit 0: This bit is the Delta Clear to Send (DCTS) indicator. Bit 0 indicates that the $\overline{CTS}$ input to the chip has changed state since the last time it was read by the CPU.

Bit 1: This bit is the Delta Data Set Ready (DDSR) indicator. Bit 1 indicates that the $\overline{DSR}$ input to the chip has changed state since the last time it was read by the CPU.

Bit 2: This bit is the Trailing Edge of Ring Indicator (TERI) detector. Bit 2 indicates that the $\overline{RI}$ input to the chip has changed from an On (logic 1) to an Off (logic 0) condition.

Bit 3: This bit is the Delta Received Line Signal Detector (DRLSD) indicator. Bit 3 indicates that the $\overline{RLSD}$ input to the chip has changed state.

NOTE

Whenever bit 0, 1, 2, or 3 is set to logic 1, a MODEM Status interrupt is generated.

Bit 4: This bit is the complement of the Clear to Send ($\overline{CTS}$) input. If bit 4 (loop) of the MCR is set to a 1, this bit is equivalent to RTS in the MCR.

Bit 5: This bit is the complement of the Data Set Ready ($\overline{DSR}$) input. If bit 4 of the MCR is set to a 1, this bit is equivalent to DTR in the MCR.

Bit 6: This bit is the complement of the Ring Indicator ($\overline{RI}$) input. If bit 4 of the MCR is set to a 1, this bit is equivalent to OUT 1 in the MCR.

Bit 7: This bit is the complement of the Received Line Signal Detect ($\overline{RLSD}$) input. If bit 4 of the MCR is set to a 1, this bit is equivalent to OUT 2 of the MCR.

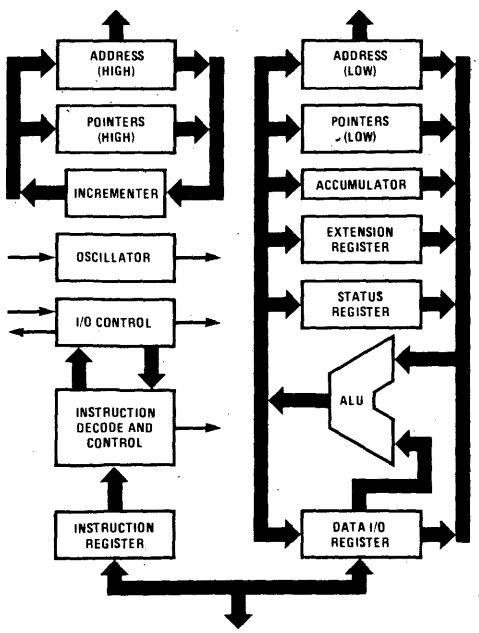
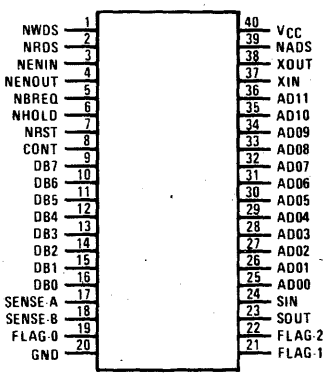
INS8060 Single-Chip 8-Bit N-Channel Microprocessor (SC/MP Family)

General Description



The INS8060 is the N-channel version of National's SC/MP family (an acronym for Simple, Cost-effective MicroProcessor). This family consists of single-chip, 8-bit microprocessors packaged in standard 40-pin dual-in-line packages. N-channel, silicon gate, depletion mode standard-process technology gives the INS8060 high performance, high reliability, and high producibility.



The INS8060 is intended for use in general-purpose applications where cost per function is the most significant criterion. But cost efficiency is only a part of the INS8060's story. It goes on to include a variety of useful functions that are not even provided by some of the expensive microprocessors, like self-contained timing circuitry, 16-bit (65k) addressing capability, serial or parallel data-transfer capability and common memory/peripheral instructions. The built-in features in conjunction with the low initial cost describe what the INS8060 really is — a microprocessor specifically designed to provide the simplest and most efficient solution to many application requirements.

Features

- Simple interfacing
  - Bidirectional TRI-STATE® 8-bit data bus
  - TTL-compatible input/output interface
- Silicon-gate N-channel ion-implant process
- Direct Memory Access (DMA) and multiprocessor capabilities
  - Handshake bus-access control on chip
- Simplified programming
  - Multiple addressing modes — program-counter-relative, immediate data, indexed, auto-indexed, and implied
- Direct control output
  - Three user-accessible control-flag outputs
- Simple I/O hardware
  - Separate serial-data input and output ports
  - Two sense inputs
  - Direct interfacing to standard memory parts
- Simple timing hardware
  - On-chip clock generator
- Interface flexibility
  - Capability to interface with memories or peripherals of any speed
- Large system capability
  - Address capability to 65k bytes of memory
- Simplified power requirements
  - Single 5-volt supply
  - Low power
- Low Cost
  - Plastic package

Block and Connection Diagrams

INS8060 Pin Configuration

© 1978 National Semiconductor Corp.

DA-B2M88/Printed in U.S.A.

Functional Description

The INS8060 is a self-contained general-purpose microprocessor designed for ease of implementation in stand-alone, DMA (Direct Memory Access), and multiprocessor applications. Communications between the INS8060 and external memory/peripheral devices are effected via a 12-bit dedicated address bus and an 8-bit bidirectional data bus. During the address interval of each input/output cycle, the INS8060 employs both busses to provide a 16-bit address output: the 12 least significant address bits are sent out over the 12-bit address bus and the 4 most significant address bits (DB3-DB0) are sent out over the 8-bit data bus along with 4 status bits (DB7-DB4). Separate strobe outputs from the INS8060 (NADS, NWDS, NRDS) indicate when valid address information is present on the two busses, and when valid input/output memory or peripheral data are present on the 8-bit bus. To further extend application flexibility serial data input/output ports are also provided so that serial data transfers can be effected under program control. The remaining input/output signals shown in figure 1 are dedicated to general-purpose control and status functions, including initialization, bus management, microprocessor halt, interrupt request, input/output cycle extension, and user-specified hardware/software interface functions. A detailed description of each input/output signal is provided in table 1.

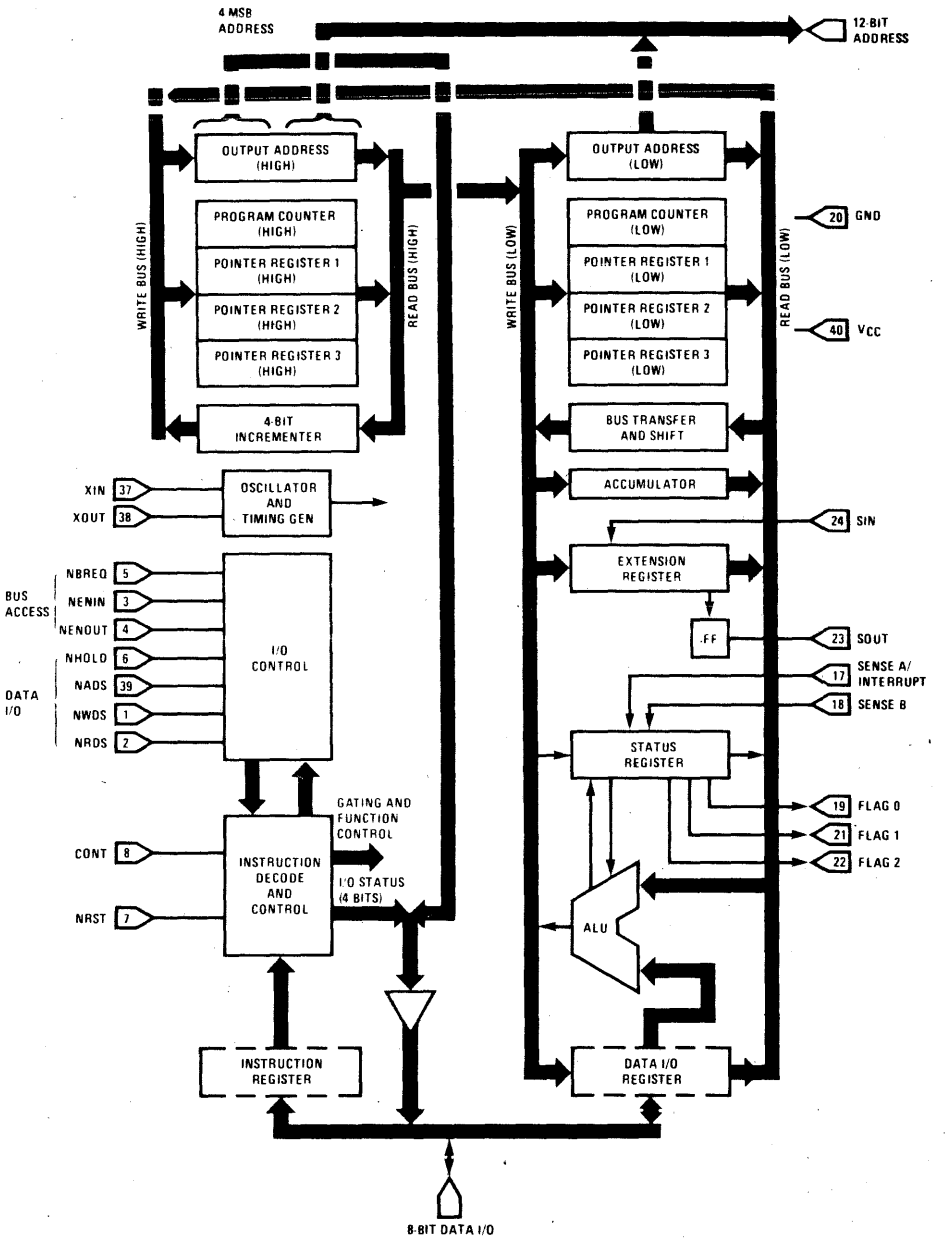


FIGURE 1. INS8060 Detailed Block Diagram

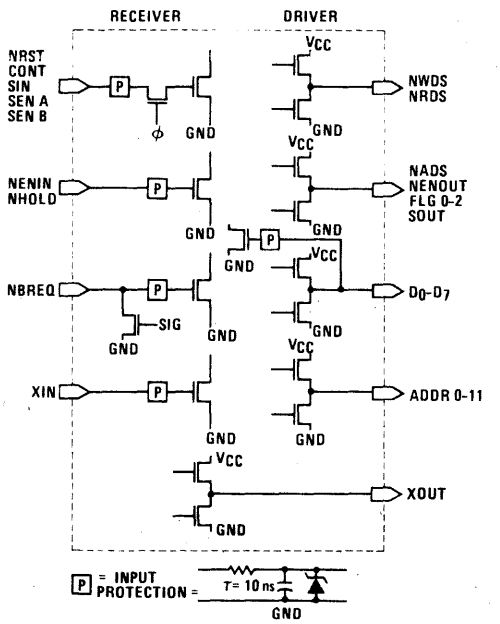
©IC MASTER 1979

TABLE 1. Input/Output Signal Description

Signal Mnemonic	Functional Name	Description
NRST	Reset Input	Set high for normal operation. When set low, aborts in-process operations. When returned high, internal control circuit zeroes all programmer-accessible registers; then, first instruction is fetched from memory location 0001_{16}.
CONT	Continue Input	When set high, enables normal execution of program stored in external memory. When set low, the INS8060 operation is suspended (after completion of current instruction) without loss of internal status.
NBREQ	Bus Request Input/Output	Associated with the INS8060 internal allocation logic for system bus. Can be used as bus request output or bus busy input. Requires external load resistor to V_{CC}.
NENIN	Enable Input	Associated with the INS8060 internal allocation logic for system bus. When set low, the INS8060 is granted access to system busses. When set high, places the INS8060's bus pins in high-impedance (TRI-STATE®) mode.
NENOUT	Enable Output	Associated with INS8060 internal allocation logic for system bus. Set low when NENIN is low and the INS8060 is not using system busses (NBREQ-high). Set high at all other times.
NADS	Address Strobe Output	Active-low strobe. While low, indicates that valid address and status output are present on system busses.
NRDS	Read Strobe Output	Active-low strobe. On trailing edge, data are input to the INS8060 from 8-bit bidirectional data bus. High-impedance (TRI-STATE®) output when input/output cycle is not in progress.
NWDS	Write Strobe Output	Active-low strobe. While low, indicates that valid output data are present on 8-bit bidirectional data bus. High-impedance (TRI-STATE®) output when input/output cycle not in progress.
NHOLD	Input/Output Cycle Extend Input	When set low prior to trailing edge of NRDS or NWDS strobe, stretches strobe to extend input/output cycle; that is, strobe is held low until NHOLD signal is returned high.
SENSE A	Sense/Interrupt Request Input	Serves as interrupt request input when the INS8060 internal IE (Interrupt Enable) flag is set. When IE flag is reset, serves as user-designated sense condition input. Sense condition testing is effected by copying status register to accumulator.
SENSE B	Sense Input	User-designated sense-condition input. Sense-condition testing is effected by copying status register to accumulator.
SIN	Serial Input to E Register	Under software control, data on this line are right-shifted into E register by execution of SIO instruction.
SOUT	Serial Output from E Register	Under software control, data are right-shifted onto this line from E register by execution of SIO instruction. Each data bit remains latched until execution of next SIO instruction.
FLAGS 0, 1, 2	Flag Outputs	User-designated general-purpose flag outputs of status register. Under program control, flags can be set and reset by copying accumulator to status register.
AD00-AD11	Address Bit 00 through Address Bit 11	Twelve TRI-STATE® address output lines. The INS8060 outputs 12 least significant address bits on this bus when NADS strobe is low. Address bits are then held valid until trailing edge of read (NRDS) or write (NWDS) strobes. After trailing edge of NRDS or NWDS strobe, bus is set to high-impedance (TRI-STATE®) mode until next NADS strobe.

NOTE:



The 8-bit bidirectional data bus is set to the high-impedance (TRI-STATE®) mode except when it is actually in use by the INS8060 (NADS, NRDS, or NWDS low). During the addressing interval of each input/output cycle (NADS low), the INS8060 provides address and status outputs over the bus; during the ensuing data-transfer interval (NRDS or NWDS low), 8-bit input or output data bytes are routed over the bus.

TABLE 1. Input/Output Signal Description (Continued)

Signal Mnemonic/ Pin Designation	Output at NADS Time		Input at NRDS Time	Output at NWDS Time
	Functional Name	Description		
DB0	Address Bit 12	Fourth most significant bit of 16-bit address.	Input data are expected on the eight (DB0-DB7) lines.	Output data are valid on the eight (DB0-DB7) lines.
DB1	Address Bit 13	Third most significant bit of 16-bit address.		
DB2	Address Bit 14	Second most significant bit of 16-bit address.		
DB3	Address Bit 15	Most significant bit of 16-bit address.		
DB4	R-Flag	When high, data input cycle is starting; when low, data output cycle is starting.		
DB5	I-Flag	When high, first byte of instruction is being fetched.		
DB6	D-Flag	When high, indicates delay cycle is starting; that is, second byte of DLY instruction is being fetched.		
DB7	H-Flag	When high, indicates that Halt Instruction has been executed. (In some system configurations, the H-Flag output is latched and, in conjunction with the CONTinue input, provides a programmed halt.)	**Note:** The DB0 through DB7 (AD12-HFLG) lines are a high-impedance (open circuit) load when the INS8060 does not have access to the input/output bus.	

DRIVERS AND RECEIVERS

Equivalent circuits for the INS8060 drivers and receivers are shown below. All inputs have static charge protection circuits consisting of an RC filter and voltage clamp. These devices still should be handled with care, as the protection circuits can be destroyed by excessive static charge.

INS8060 Driver and Receiver Equivalent Circuits

TIMING CONTROL

All necessary timing signals are provided by a three-stage inverter ring oscillator contained on the INS8060 chip. Two control pins, XIN and XOUT, permit the frequency of the oscillator to be controlled by any of the following methods:

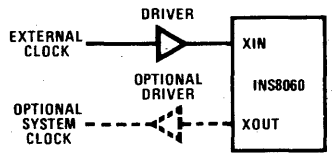
1. Leave the XOUT pin unterminated and drive the XIN pin with an externally generated TTL clock that conforms to the parameters shown in figure 2A. For this method, the frequency of the oscillator is equal to the frequency of the external clock input.
2. Connect a resistor-capacitor feedback network between the XIN and XOUT pins and GND as shown in figure 2B.
3. Connect a crystal with low-pass filter network between the XIN and XOUT pins and GND as shown in figure 2C (for above 1 megahertz) or figure 2D (for 1 megahertz or below). For this method, the frequency of the oscillator is equal to the resonant frequency of the crystal and the low-pass filter prevents unwanted harmonic oscillations.

In addition to illustrating appropriate frequency-control networks for the on-chip oscillator, figures 2A through 2D also show how an optional driver may be used to derive a system clock from the oscillator signal present at the XOUT pin.

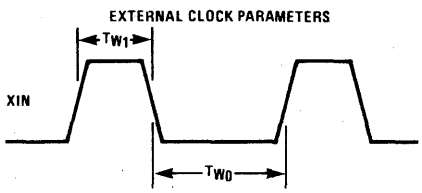
In the discussions that follow, instruction execution and input/output timing are described in terms of microcycles.

©IC MASTER 1979

The time interval of a microcycle is four times the period of the oscillator; that is:

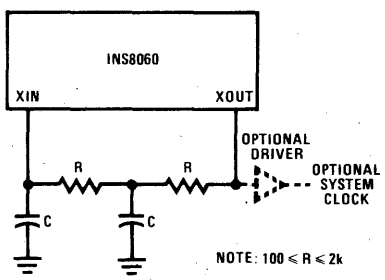


period of one microcycle = $2T_C$

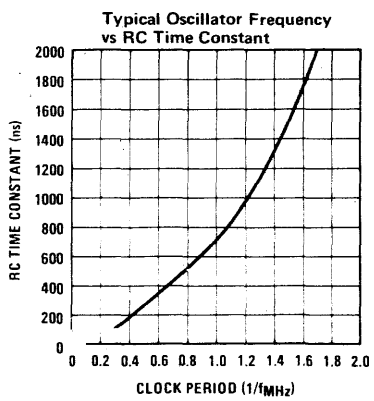


$$T_C = 2\left(\frac{1}{f_{osc}}\right) = 2\left(\frac{1}{f_{res}}\right) = 2\left(\frac{1}{f_{XIN}}\right)$$

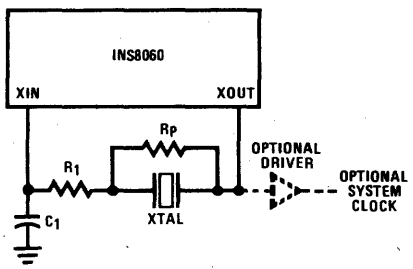
where:



T_C = time period for two cycles of on-chip or external oscillator
f_{osc} = frequency on on-chip oscillator
f_{res} = resonant frequency of crystal connected between XIN and XOUT pins
f_{XIN} = frequency of external clock applied to XIN pin

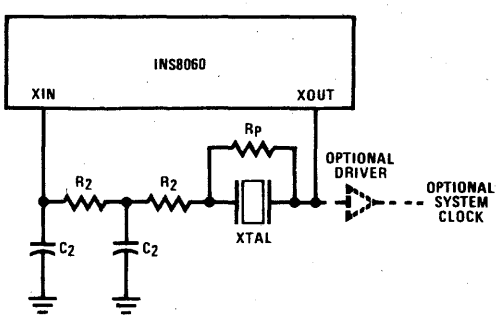


A. External Clock Input



B. Resistor-Capacitor Feedback Network

C. Crystal with Low-Pass Filter (Above 1MHz)



Suggested values for Crystal with Low-Pass Filter Network (Above 1 MHz)

Crystal	Rp	C_1	R_1
2MHz	100kΩ	56pF	1kΩ
3.58MHz	100kΩ	27pF	1kΩ
4MHz	100kΩ	27pF	1kΩ

XTAL is parallel resonant with maximum series resonance equal to 1kΩ.

D. Crystal with Low-Pass Filter (1MHz or Below)

Suggested values for Crystal with Low-Pass Filter Network (1 MHz or Below)

Crystal	Rp	C_2	R_2
100 kHz	1 MΩ	1000 pF	2 kΩ
200 kHz	1 MΩ	1000 pF	1 kΩ
500 kHz	1 MΩ	1000 pF	1 kΩ
700 kHz	1 MΩ	500 pF	2 kΩ
1 MHz	1 MΩ	120 pF	1 kΩ

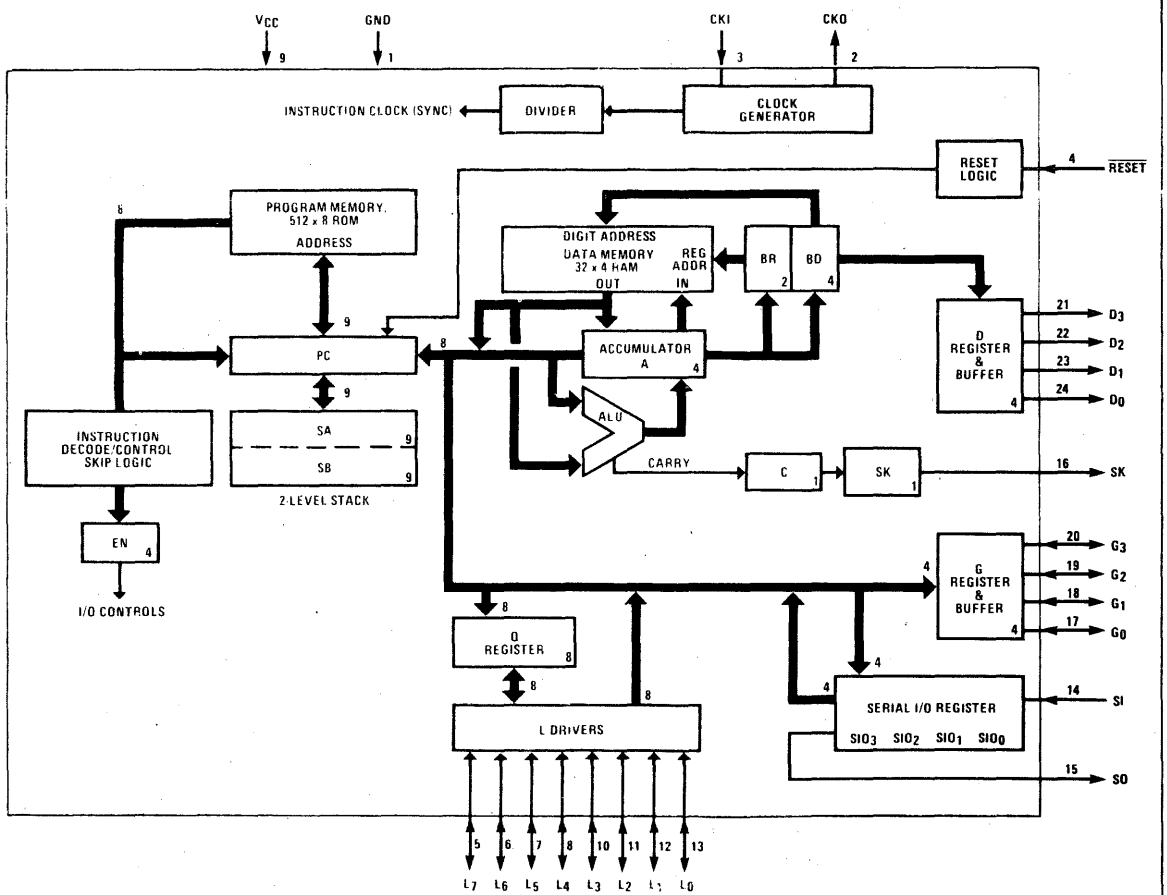
COP410L Single-Chip N-Channel Microcontroller



General Description

The COP410L Single-Chip N-Channel Microcontroller is a member of the Control Oriented Processor (COP) family, fabricated using N-channel, silicon gate MOS technology. It is a complete microcomputer containing all system timing, internal logic, ROM, RAM and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. It is an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized Control Oriented processor at a low end-product cost.

Features

- Low cost
- Powerful instruction set
- 512 x 8 ROM, 32 x 4 RAM
- 19 I/O lines
- Two-level subroutine stack
- 16μs instruction time
- Single wide-range supply (4.5 - 9.5V)
- Low current drain (6mA max)
- Internal binary counter register with serial I/O capability
- General purpose and TRI-STATE® outputs
- LSTTL/CMOS compatible in and out
- Direct drive of LED digit and segment lines
- Software/hardware compatible with other members of COP400 family
- Extended temperature range device available (-40°C to +85°C)

Connection Diagrams

Functional Characteristics

Oscillator

There are four basic clock oscillator configurations:

a. Ceramic Resonator Controlled Oscillator.

b. External Oscillator.

c. RC Controlled Oscillator.

d. Externally Synchronized Oscillator.

I/O Options

COP outputs have the following optional configurations:

a. **Standard** — an active device to ground in conjunction with a pull-up to V_{CC}, compatible with LSTTL and CMOS input requirements.

b. **Open-Drain** — an active device to ground only, allowing external pull-up as required by the user's application.

c. **Push-Pull** — an active device to ground in conjunction with a pull-up paralleled by an active device to V_{CC}. This configuration has been provided to allow for fast rise and fall times when driving capacitive loads.

d. **LED Direct Segment Drive** — an active device to ground and to V_{CC}, meeting the typical current sourcing requirements of the segments of an LED display.

e. **LED Direct Digit Drive** — a high-current device to ground, meeting the current sinking needs of a small LED digit.

f. **TRI-STATE® Push-Pull** — an active device to ground and V_{CC} intended to meet the requirements associated with connection of these outputs to a data bus shared by other bus drivers.

CKO Pin Options

In a resonator controlled oscillator system, CKO is used as an output to the resonator network. As an option CKO can be a general purpose input. As another option, CKO can be a RAM power supply pin (V_R), allowing its connection to a standby/backup power supply to maintain the integrity of RAM data with minimum power drain (1.5mA maximum at 3.3V).

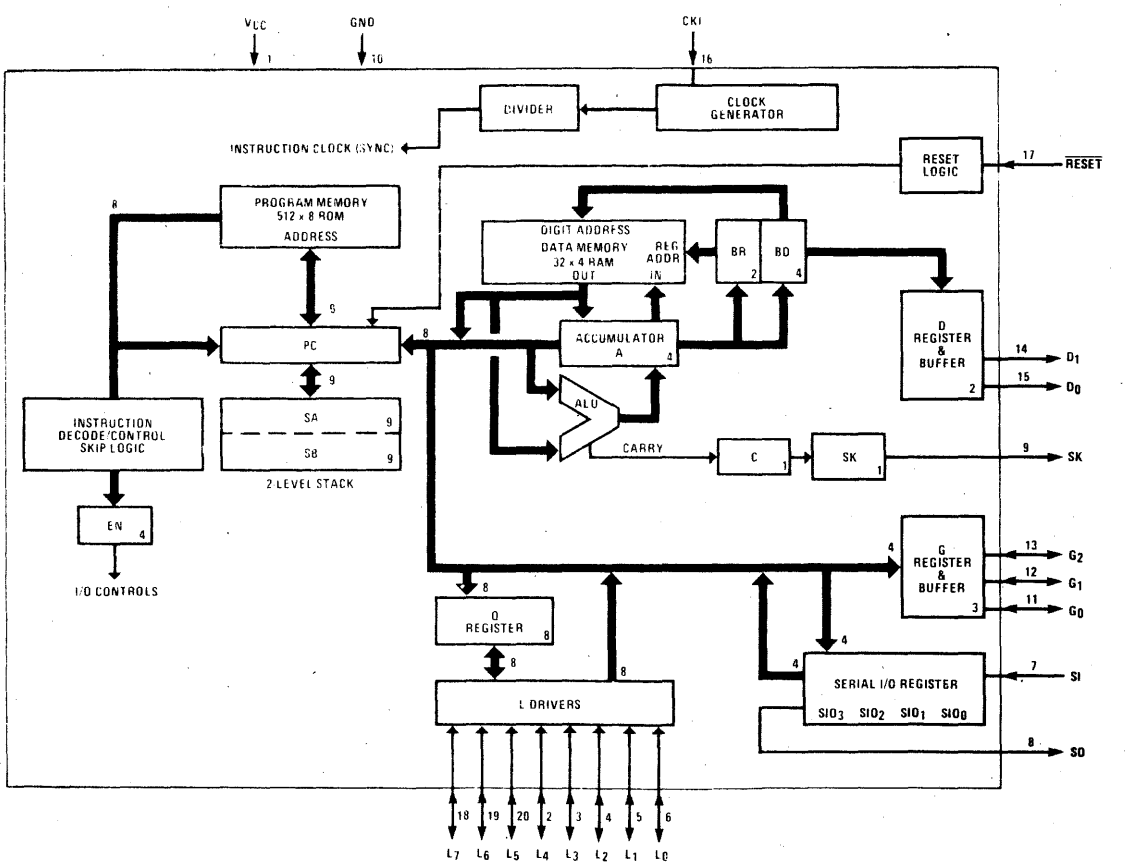
COP411L Single-Chip N-Channel Microcontroller



General Description

The COP411L Single-Chip N-Channel Microcontroller is the smallest and lowest-cost member of the Control Oriented Processor (COP) family, fabricated using N-channel, silicon gate MOS technology. It is a complete microcomputer containing all system timing, internal logic ROM, RAM and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. It is an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized Control Oriented processor at a low end-product cost.

Features

- Lowest cost!
- Narrow, 20-pin dual-in-line package
- Powerful instruction set
- 512 x 8 ROM, 32 x 4 RAM
- 16 I/O lines
- Two-level subroutine stack
- 16 μs instruction time
- Single wide-range supply (4.5 - 9.5 V)
- Low current drain (6 mA max)
- Internal binary counter register with serial I/O capability
- General purpose and TRI-STATE* outputs
- LSTTL/CMOS compatible in and out
- LED direct drive outputs
- Software/hardware compatible with other members of COP400 family
- Extended temperature range device available (- 40 °C to + 85 °C)

COP411L Block Diagram

Connection Diagram

Functional Characteristics

Oscillator

There are two basic clock oscillator configurations:

a. External Oscillator.

b. RC Controlled Oscillator.

I/O Options

COP outputs have the following optional configurations:

a. **Standard** — an active device to ground in conjunction with a pull-up to V_{CC}, compatible with LSTTL and CMOS input requirements.

b. **Open-Drain** — an active device to ground only, allowing external pull-up as required by the user's application.

c. **Push-Pull** — an active device to ground in conjunction with a pull-up paralleled by an active device to V_{CC}. This configuration has been provided to allow for fast rise and fall times when driving capacitive loads.

d. **LED Direct Segment Drive** — an active device to ground and to V_{CC}, meeting the typical current sourcing requirements of the segments of an LED display.

e. **LED Direct Digit Drive** — a high-current device to ground, meeting the current sinking needs of a small LED digit.

f. **TRI-STATE® Push-Pull** — an active device to ground and V_{CC} intended to meet the requirements associated with connection of these outputs to a data bus shared by other bus drivers.

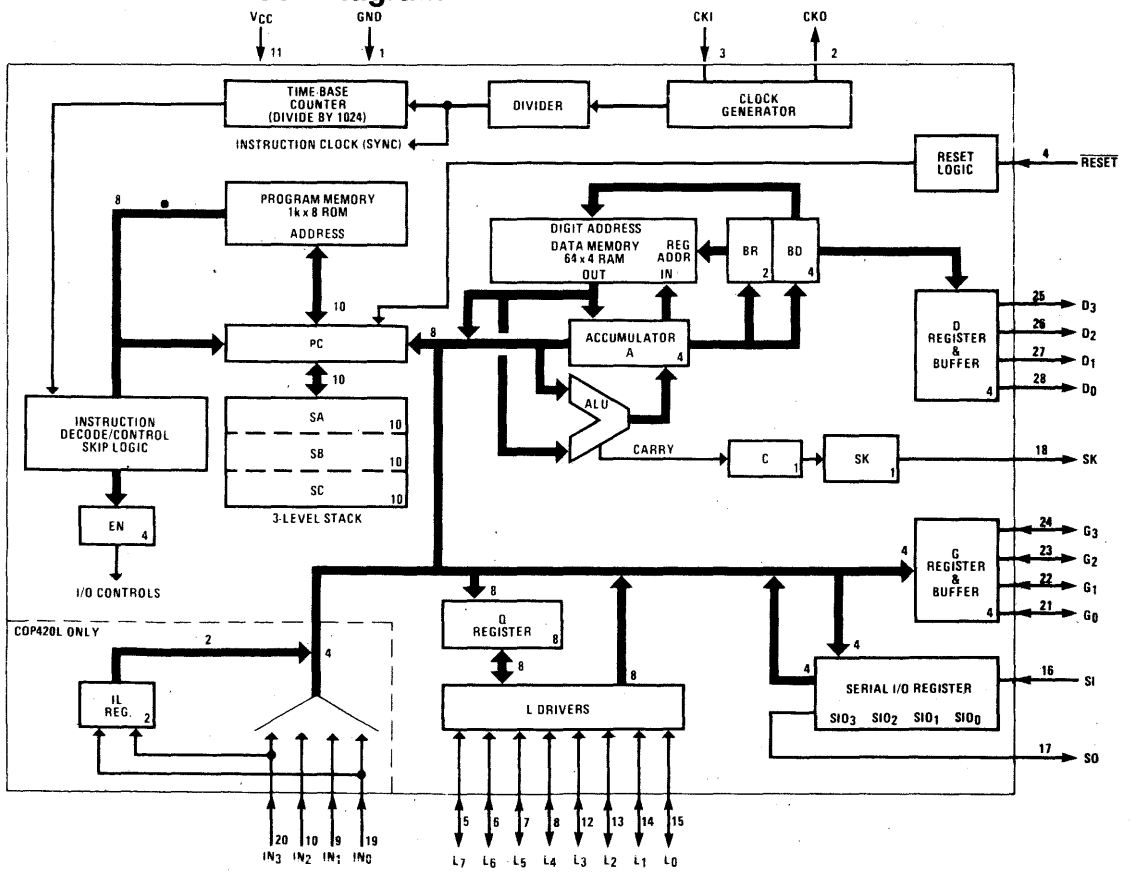
COP420L/COP421L Single-Chip N-Channel Microcontrollers



General Description

The COP420L and COP421L Single-Chip N-Channel Microcontrollers are members of the Control Oriented Processor (COP) family, fabricated using N-channel, silicon gate MOS technology. They are complete microcomputers containing all system timing, internal logic, ROM, RAM and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. The COP421L is identical to the COP420L, except with 19 I/O lines instead of 23. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized Control Oriented processor at a low end-product cost.

Features

- Low cost
- Powerful instruction set
- 1k x 8 ROM, 64 x 4 RAM
- 23 I/O lines (COP420L)
- True vectored interrupt, plus restart
- Three-level subroutine stack
- 16 μs instruction time
- Single wide-range supply (4.5 - 9.5V)
- Low current drain (8 mA max)
- Internal time-base counter for real-time processing
- Internal binary counter register with serial I/O capability
- General purpose and TRI-STATE® outputs
- LS TTL/CMOS compatible in and out
- Direct drive of LED digit and segment lines
- Software/hardware compatible with other members of COP400 family
- Extended temperature range device available (−40 °C to +85 °C)

Connection Diagrams

Functional Characteristics

Oscillator

There are four basic clock oscillator configurations:

a. Crystal Controller Oscillator.

b. External Oscillator.

c. RC Controlled Oscillator.

d. Externally Synchronized Oscillator.

I/O Options

COP outputs have the following optional configurations:

a. **Standard** — an active device to ground in conjunction with a pull-up to V_{CC}, compatible with LSTTL and CMOS input requirements.

b. **Open-Drain** — an active device to ground only, allowing external pull-up as required by the user's application.

c. **Push-Pull** — an active device to ground in conjunction with a pull-up paralleled by an active device to V_{CC}. This configuration has been provided to allow for fast rise and fall times when driving capacitive loads.

d. **LED Direct Segment Drive** — an active device to ground and to V_{CC}, meeting the typical current sourcing requirements of the segments of an LED display.

e. **LED Direct Digit Drive** — a high-current device to ground, meeting the current sinking needs of a small LED digit.

f. **TRI-STATE® Push-Pull** — an active device to ground and V_{CC} intended to meet the requirements associated with connection of these outputs to a data bus shared by other bus drivers.

CKO Pin Options

In a crystal controlled oscillator system, CKO is used as an output to the crystal network. As an option CKO can be a general purpose input. As another option, CKO can be a RAM power supply pin (V_R), allowing its connection to a standby/backup power supply to maintain the integrity of RAM data with minimum power drain (3mA maximum at 3.3V).

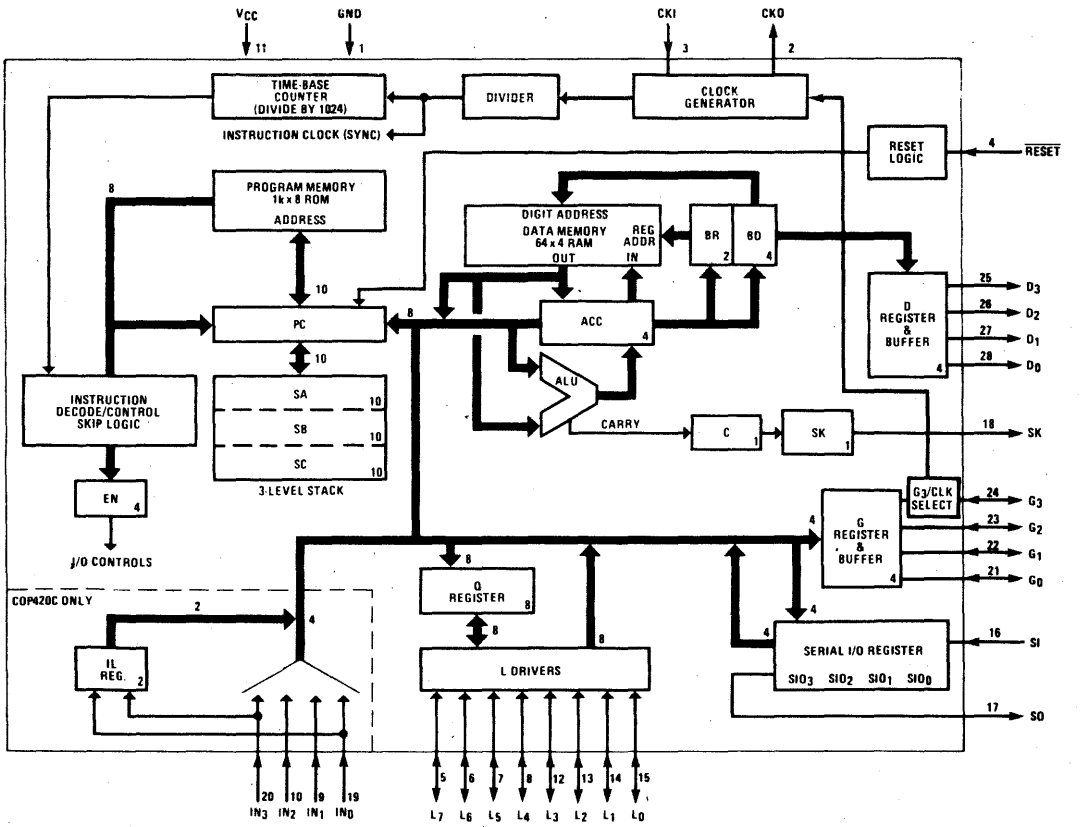
COP420C/COP421C Single-Chip CMOS Microcontrollers



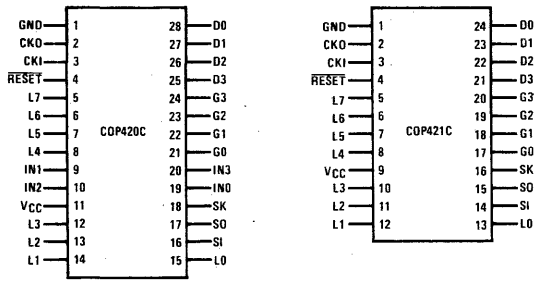
General Description

The COP420C and COP421C Single-Chip CMOS Microcontrollers are members of the Control Oriented Processor (COP) family, fabricated using Complementary MOS technology. They are complete microcomputers containing all system timing, internal logic, ROM, RAM and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. The COP421C is identical to the COP420C, except with 19 I/O lines instead of 23. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized Control Oriented processor at a low end-product cost.

Features

- Lowest power dissipation (65 μW)
- Full Military temperature range (−55 °C to +125 °C)
- Powerful instruction set
- 1k x 8 ROM, 64 x 4 RAM
- 23 I/O lines (COP420C)
- True vectored interrupt, plus restart
- Three-level subroutine stack
- 16 μs instruction time, plus software selectable oscillators
- Single supply operation (2.4 - 6.3 V)
- Internal time-base counter for real-time processing
- Internal binary counter register with serial I/O capability
- General purpose and TRI-STATE® outputs
- TTL/CMOS compatible in and out
- LED direct drive outputs
- MICROBUS™ compatible
- Software/hardware compatible with other members of COP400 family

COP420C/421C Block Diagram



© 1978 National Semiconductor Corp.

DA-B25M98/Printed in U.S.A.

©IC MASTER 1979

Connection Diagrams

Functional Characteristics

Oscillator

There are four basic clock oscillator configurations:

a. Crystal Controlled Oscillator.

b. External Oscillator.

c. RC Controlled Oscillator.

d. Externally Synchronized Oscillator.

Optionally, the user may connect a 32kHz watch crystal to CKO/CKI, and a 16μs RC combination to G3; he may then software-select between the RC oscillator for faster processing, or the crystal for minimum current drain (25μA) while maintaining a real-time clock.

I/O Options

COP outputs have the following optional configurations:

a. **Standard** — an active device to ground in conjunction with an active device to V_{CC}, compatible with LSTTL and CMOS input requirements.

b. **Open-Drain** — an active device to ground only, allowing external pull-up as required by the user's application.

c. **LED Direct Drive** — an active device to ground and to V_{CC}, meeting the typical current sourcing requirements of the segments of an LED display. The sourcing device is clamped to limit current flow.

d. **TRI-STATE® Push-Pull** — an active device to ground and V_{CC} intended to meet the requirements associated with the MICROBUS™ option. These outputs are TRI-STATE® outputs, allowing for connection of these outputs to a data bus shared by other bus drivers.

CKO Pin Options

In a crystal controlled oscillator system, CKO is used as an output to the crystal network. As an option CKO can be a general purpose input, read into bit 2 of A (accumulator) upon execution of an INIL instruction.

Power Drain

When operating at a 16μs instruction cycle, the 420C will draw 600μA at 5V. When operating at minimum speed/power (e.g., from a 32kHz watch crystal), current drain is 25μA at 2.4V (50μA at 5V), and the instruction cycle is 244μs.

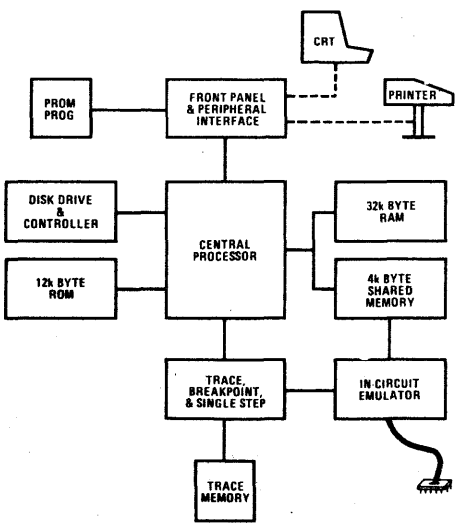
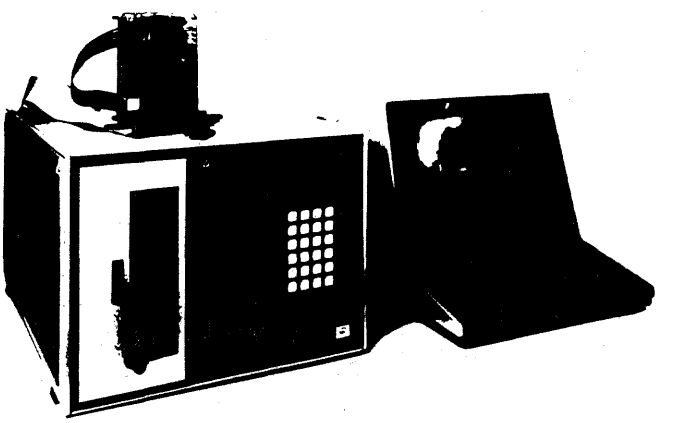
COP400-PDS Product Development System



General Description



Finally, a single development tool which supports microcontroller development activities through every phase from concept to production. The COP400 Product Development System is built around a powerful 16-bit microcomputer to allow rapid execution of sophisticated, efficient utilities. The system meets the *total* product development need. An editor and assembler are provided to handle source code entry, conversion to object code and maintenance of documentation. The emulator card attachment allows object code to be executed under the careful control of the COPMONITOR debug utility. A cable can be connected from the PDS to the final product; in this mode, the full power and versatility of the PDS is extended to the product-to-be during its research and development phase. When a program is complete and ready to be committed to production, the PDS generates a transmittal disk that NSC will use to assure accurate masking of the final components. The usefulness of the PDS does not end there: a fixture is available for the incoming functional test of the ROM programmed COP400 devices. Thus, the COP400-PDS actively supports every step of a microcontroller product development activity.

Features

- Supports the entire COP400 microcontroller family
- A *total* concept-to-production tool
- Low cost
- 32k bytes R/W memory
- 12k bytes PROM (firmware)
- Disk-based
- Macro-assembler
- RS-232 and current loop peripheral interfaces
- Automatic baud rate selection (110-9600)
- Comprehensive in-circuit emulation (ICE), with single-step, breakpoint & trace
- Functional test module for incoming inspection
- ROM pattern transmission by disk

System Diagram

© 1978 National Semiconductor Corp.

DA-B25M98/Printed in U.S.A.

©IC MASTER 1979

COP400 Product Development System

FIRMWARE (ROM)

Executive

- Entered on a power-up or initialization.
- Provides for system definition.
- Allows loading and executing disk based programs by file name.

Diagnostics

- Memory address, bit and word test.
- CPU operation.
- Disk read test.
- Diagnostics are called by pressing diag. button on front panel.

SOFTWARE (Disk)

File Manager

- Create and delete disk files.
- Control file directory.
- Protect disk files.
- Pack disk files.
- Copy disk to disk.

DSKIT

- Initialize disk.
- Disk read/write diagnostic.

COP Monitor

- In-circuit emulator (ICE).
- Software breakpoints.
- External hardware breakpoint (2 lines).
- Lists user specified registers when selected breakpoint is detected.
- Real-time trace operation displays 256 address sequences. Synchronization may be pre, post or center and may be software or external event initiated.
- Mnemonic modification of object code.
- Single step.
- Step-list-restart.
- PROM programmer is built into the COP400-PDS front panel.
- UV erasable PROMs (MM5204Q).
- Single supply bipolar PROMs (DM74S296).

Editor

- Read text from disk or terminal.
- Display text on terminal.
- Write edited text to disk or printer.
- Generate source code for assemblers.
- Extensive word processing functions.
- Edit source files larger than the edit buffer.

Macro Assembler

- Macro generation capabilities.
- Listing controls.
- Conditional assembly operators.
- Wide variety of directives.
- Diagnostic messages that include error position in source line.
- MASKTRAN creates a disk file for transmission of customer ROM patterns and device I/O options to National Semiconductor.

PERIPHERALS

- The COP400-PDS will interface to a wide range of peripheral devices.
- Both RS-232 and current loop ports are provided.
- Console interface.
- Printer interface (RS-232 serial).
- Emulator card for in-circuit emulation.
- Functional test module for incoming inspection.

SYSTEM COMPONENTS

COP400-PDS

- Host microprocessor.
- 32k byte R/W memory.
- Single disk drive.
- System power supply.
- 12k byte ROM (all firmware described).
- Emulator cable.
- External connectors (3).
- Two master diskettes (all software described).
- Operator's Manual.
- PROM programmer.

Emulator Card

An emulator card is ordered separately for each of the COPS family of devices to be used. The emulator card allows real-time emulation in your applications circuitry using PROM memory or the development system R/W memory for program storage.

- PC assembly with the appropriate COP400 ROMless device and its support circuitry.
- Sockets for UV erasable or fusible link PROMs.
- In-circuit emulation cable with emulated COP device plug.
- The emulator card is shipped assembled and tested.

Video Display Terminal

The video display unit operates at baud rates from 110 to 9600. It provides keyboard input and video output for source program entry and editing, and system software operation.

Ordering Information

U.S. Version (60 Hz, 120 V_{AC}):
Part Number COP400-PDS.

European Version (50 Hz, 220 V_{AC}):
Part Number COP400-PDSE

- Video display terminal:
  Part Number COP400-842.
- COP420 emulator board:
  Part Number COP400-E02
- Master diskettes:
  Part Number COP400-D01.
- Operator's Manual:
  Publication Number 420305548-001.
- Incoming inspection test unit Part number COP400-T01 Available March 1979.

COP402/COP402M ROMless N-Channel Microcontrollers

General Description

The COP402 and COP402M ROMless Microcontrollers are members of the Control Oriented Processor (COP) family, fabricated using N-channel silicon gate MOS technology. Each part contains CPU, RAM and I/O, and is identical to a COP420 device, except the ROM has been removed; pins have been added to output the ROM address and to input ROM data. In a system, the COP402 or 402M will perform exactly as the COP420; this important benefit facilitates development and debug of a COP420 program prior to masking the final part. These devices are also appropriate in low volume applications, or when the program may require changing. The COP402M is identical to the COP402, except the MICROBUS™ interface option has been implemented.

The COP402 may also be used to emulate the COP410L, 411L, 420L or 420C by appropriately reducing the clock frequency.

Features

- Low cost
- Exact circuit equivalent of COP420
- Standard 40-pin dual-in-line package
- Interfaces with standard PROM or ROM
- 64×4 RAM, addresses up to 1k×8 ROM
- MICROBUS™ compatible (COP402M)
- Powerful instruction set
- True vectored interrupt, plus restart
- Three-level subroutine stack
- 4.0μs instruction time
- Single supply operation (4.5V to 6.3V)
- Internal time-base counter for real-time processing
- Internal binary counter register with serial I/O capability
- Software/hardware compatible with other members of COP400 family

Absolute Maximum Ratings

Voltage at Any Pin Relative to GND	−0.5V to +7V
Ambient Operating Temperature	0°C to +70°C
Ambient Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10 seconds)	300°C
Power Dissipation	0.75 Watt at 25°C 0.4 Watt at 70°C

Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics $0°C \leq T_A \leq +70°C$, $4.5V \leq V_{CC} \leq 6.3V$ unless otherwise noted.

Parameter	Conditions	Min	Max	Units

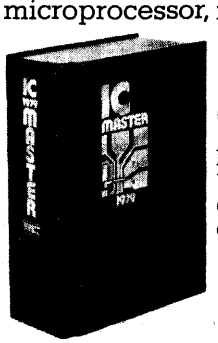
"I need to know if this device exists, and if there are any alternate sources. Where do I start?"

- Memory IC
- RAM
- Static
- 1024x1
- CMOS
- 250 Nanoseconds
- 5 Volts

If you're spending hours to solve a problem similar to the one above, you're behind the times...



It only takes a few seconds with "THE MASTER."

Clear your desk for action with the newly revised 1979 IC Master. Its all-under-one-cover features include: Over 40,000 standard products from more than 87 different companies... five different selection guides (memory, microprocessor, interface, linear and digital.) ... alternate source directory for pin- for- pin, function- for- function replacements ... applications directory... complete military section ... a complete part numbering guide ... etc.

You don't have to search through stacks of catalogs. Simply look up the specs and function you need. You don't need a part number to start with.

All you need is a problem to use The Master. Does the device exist? Who makes it? Is there an alternate source? What's the part number? Is there an applications note? Who is my closest distributor—etc.

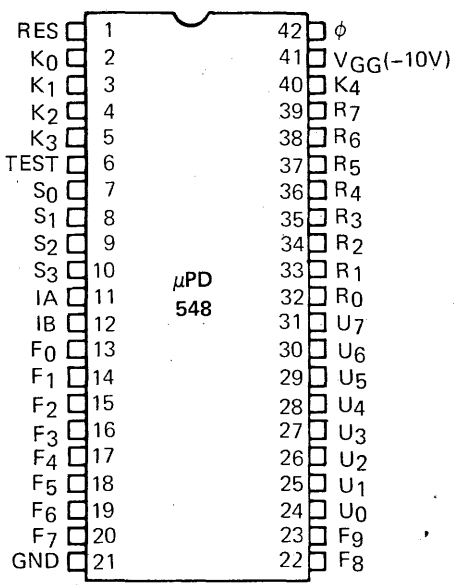
μCOM-42 4-BIT SINGLE CHIP MICROCOMPUTER

DESCRIPTION

The μCOM-42 (Part No. μPD548) is a single chip microcomputer that is ideally suited for Electronic Cash Register (ECR), Point of Sale (POS) and Electronic Scale applications.

Containing a 4-bit Parallel ALU, ROM for program storage and RAM for data storage, the μCOM-42 provides an economical and simple solution to many Vending/Calculating requirements.



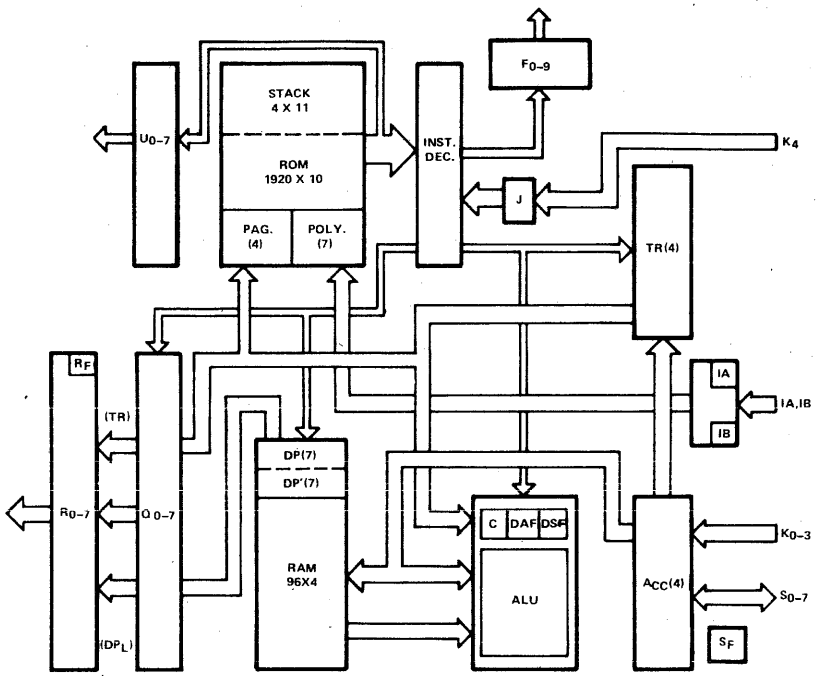
Because of its extensive instruction set and five input/output ports, the μCOM-42 is capable of controlling an 8 x 4 keyboard, an 8 digit display and low cost ECR-type printers.

Finally, the on-chip RAM space can be augmented by an external CMOS RAM for applications requiring low power data retention.

FEATURES

- Stand Alone 4-bit Microcomputer
- All 72 Instructions are Single Byte
- 10 μsec Instruction Cycle
- 1920 x 10-Bit Program Memory (ROM)
- 96 x 4-Bit Data Memory (RAM)
- 4-Level Stack
- 2 Interrupt Request Lines
- I/O Compatible with TTL
- 10 Discrete Output Ports (F_0-F_9)
- Two 8-Bit Output Ports (U_0-U_7, R_0-R_7)
- One 4-Bit Input Port (K_0-K_3)
- One 4-Bit Input/Output Port (S_0-S_3)
- One Single Bit Testable Input Port (K_4)
- Single Phase TTL Level Clock (200 KHz Max.)
- Single Supply, −10V PMOS Technology
- 42 Pin Plastic Dual-in-Line Package

PIN CONFIGURATION



PIN NAMES

RES	Reset
K_0–K_3	Input Port K
TEST	Input for Testing (Normally V_{GG})
S_0–S_3	Input/Output Port S
IA, IB	Interrupt Input Ports
F_0–F_9	Output Port F
U_0–U_7	Output Port U
R_0–R_7	Output Port R
K_4	Input Port for Condition Test
φ	Clock Input

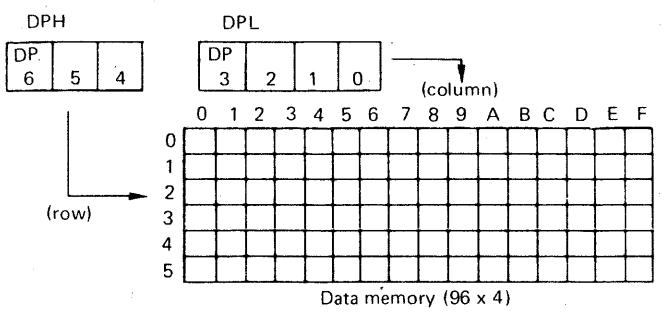
BLOCK DIAGRAM

FUNCTIONAL DESCRIPTION

Program Counter

The 11-bit program counter is composed of two sections, a 4-bit page register and a 7-bit polynomial counter. The page register selects one page out of 15, each consisting of 128 words addressed by the 7-bit polynomial counter. The contents of the page register are independent of the operation of the polynomial counter, so that it is not affected by polynomial counter overflow.

Stack Register



In order to store the program counter contents upon an interrupt or subroutine call, four 11-bit stack registers are provided to enable a combination of subroutine calls and interrupt nesting to four levels. The stack register is a LIFO (Last in, First-Out) type.

ROM (Read Only Memory)

The on-chip ROM consists of 1,920 words of ten bits each and is divided into 15 pages. A page is selected by the page register, the upper four bits of the program counter. Each page consists of 128 words addressed by the polynomial counter, the lower seven bits of the program counter.

RAM (Data Memory)

The data memory is a 96 x 4-bit RAM addressed by a 7-bit data pointer (DP). The RAM is divided into six rows of 16 4-bit columns each. The 7-bit data pointer consists of an upper 3-bit register (DPH) which selects the row address and a lower 4-bit register (DPL) which selects the column address.

Data memory (96 x 4)

©IC MASTER 1979

FUNCTIONAL DESCRIPTION (CONT.)

Internal Registers

The Accumulator (ACC) is connected with the ALU and the carry flip-flop (C) and is able to perform either binary or decimal arithmetic by testing the decimal addition flip-flop (DAF) and the decimal subtraction flip-flop (DSF). Constants are loaded into the ACC as immediate data from ROM and variable data are loaded from or exchanged with RAM. The ACC is also connected with the temporary register (TR), the parallel I/O port S and the parallel input port K. The TR is an auxiliary register used for temporary storage of 4-bit data. The Q register is an 8-bit serial-in/parallel-out shift register designed for display digit strobing and generation of printer hammer triggers.

I/O Ports

The R port is an 8-bit parallel port that may be loaded from the Q register for digit strobing or loaded with the 4-bit TR and the 4-bit DPL for external RAM addressing. The U port is an 8-bit parallel port that is loaded with immediate data. It is usually used for outputting segment information for display and digit information for key scanning. The K port is a 4-bit input port that is usually used for key scan input. The K4 port is a single bit port that is testable by software. The S port is a 4-bit parallel I/O port that is typically used as the data bus to external RAM. The F port consists of ten discrete output lines that can be individually set or reset under program control.

Interrupt Ports

Two interrupt input lines, IA and IB, are available to accept an interrupt request when interrupts are enabled. IA has a higher priority level than IB. Thus when concurrent interrupts occur on both IA and IB only the IA interrupt is accepted and both are disabled. But a single IB interrupt disables only the IB interrupt and leaves IA enabled.

INSTRUCTION SET

The μCOM-42 has a powerful 72, 10-bit word, instruction set. All instructions are single words. There are a number of multi-function instructions which reduce the number of program steps. In addition, automatic data pointer modification, single word subroutine calls and N-way branch capability all help improve operation speed and reduce ROM requirements. The μCOM-42 instruction set is summarized below.

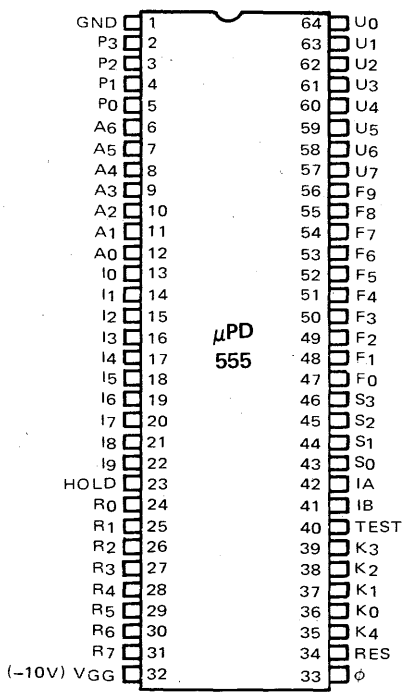
EVACHIP-42

DESCRIPTION



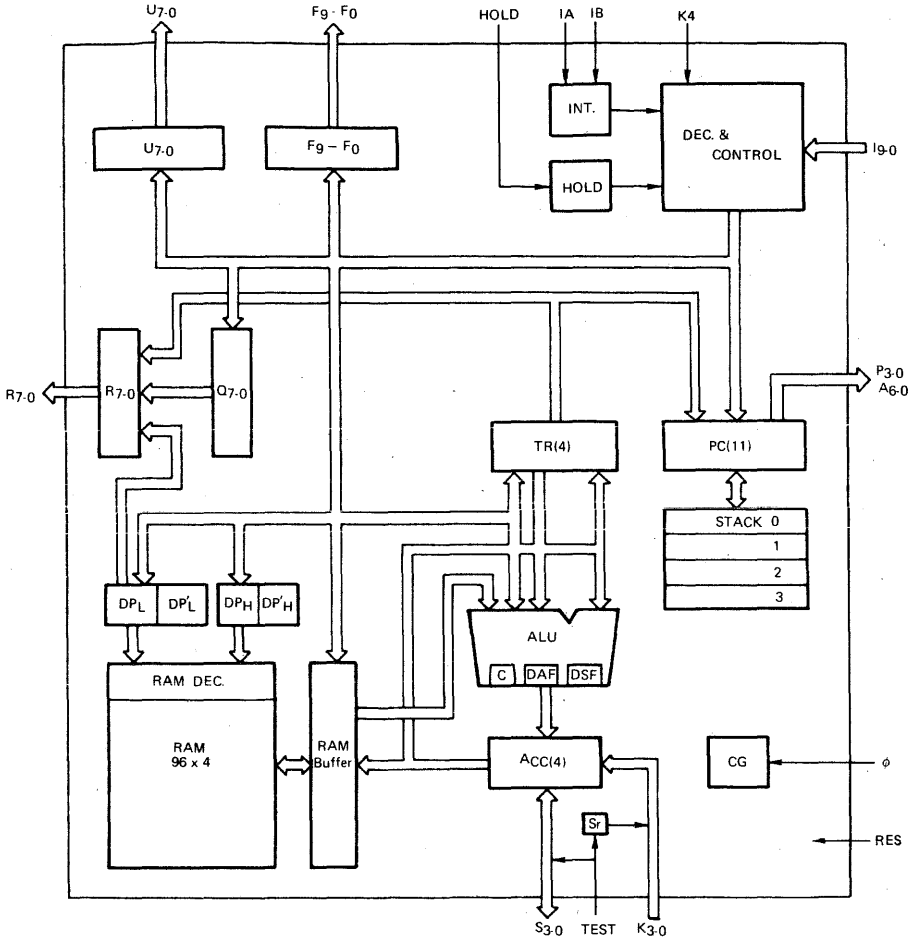
The μPD555 is a system evaluation chip designed to support both hardware and softwa debugging of the μCOM-42 (μPD548) one-chip microcomputer system.

The μPD555 and the μPD548 have the same functionality in all aspects except that the μPD555 does not contain a read only memory, but provides addressing capability to external memory and HOLD function for step-by-step operation.

FEATURES

- 4-Bit Parallel Processor
- Powerful 72 Instruction Set Including Decimal/Binary Arithmetic Operations
- 10 μs Instruction Cycle Time
- Addressing Capability up to 1920 Words by 10-Bits of External Program Memory
- 96 Words by 4-Bit Data Memory On Chip
- 4-Level Subroutines
- Two Interrupt Input Lines (IA and IB)
- HOLD Capability
- A Variety of Input/Output Ports –
  - 10 Discrete Output Ports (F_9-F_0)
  - Two 8-Bit Output Ports (U_7-U_0, R_7-R_0)
  - 4-Bit Input Port (K_3-K_0)
  - 4-Bit Input/Output Port (S_3-S_0)
    I/O Level Compatible with μPD5101
  - 1-Bit Test Input Line
- P-Channel MOS
- Open Drain Output
- Single Power Supply: −10V
- Available in a 64 Pin Ceramic Dual-in-Line Package

PIN CONFIGURATION



PIN NAMES

$P_0 - P_3$	Page Output
$A_0 - A_6$	Address Output
$I_0 - I_9$	Instruction Input
HOLD	HOLD Input
$R_0 - R_7$	Output Port R
φ	Clock Input
RES	Reset Input
K4	K4 Test Input Line
$K_0 - K_3$	K Input Port
TEST	IC Test Input
IA, IB	Interrupt Input
$S_0 - S_3$	Input/Output Port S
$F_0 - F_9$	Output Port F
$U_0 - U_7$	Output Port U

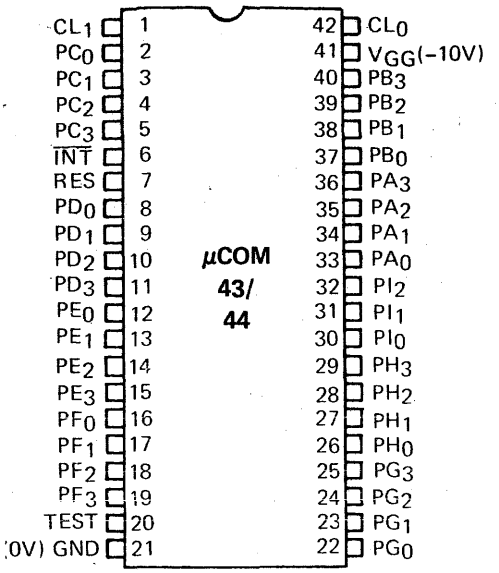
μCOM-43/44/45 4-BIT SINGLE CHIP MICROCOMPUTERS

DESCRIPTION

The μCOM-43 Family consists of three device types designed to offer a full range of cost/performance tradeoffs. All three devices share compatible hardware and instruction set. The μCOM-43 Family is designed for general purpose controller applications and offers ideal devices for industrial controls, appliance controls, games, etc.

All three devices contain the functional blocks necessary to enable their use for both industrial and non-industrial controller applications. These blocks include: a 4-bit parallel ALU; 8-bit wide ROM for program storage; 4-bit wide RAM for data storage; stack register for subroutines; extensive I/O; and an on-chip clock generator.

The instruction set of the μCOM-43 Family is designed to perform controller-oriented functions and for efficient use of the fixed program memory space. The instruction set includes a number of multifunction instructions, powerful I/O instructions including single bit manipulation, and test-and-skip instructions for conditional processing.



The three device types comprising the μCOM-43 Family are differentiated by ROM/RAM size and I/O lines. The μCOM-43 has 2000 x 8 ROM, 96 x 4 RAM and 35 I/O lines. The μCOM-44 has 1000 x 8 ROM, 64 x 4 RAM and 35 I/O lines. The μCOM-45 has 1000 x 8 or 640 x 8 ROM, 32 x 4 RAM and 21 I/O lines. In addition, the μCOM-43 has real hardware interrupt, 3 level stack and programmable timer, while the μCOM-44/45 have pseudo-interrupt capability and a single level stack.

FEATURES

- Stand Alone 4-Bit Microcomputers for Control Applications
- Powerful Instruction Set Capable of: Binary Addition; Decimal Addition and Subtraction; Logical Operations
- 10 μs Instruction Cycle
- Choice of ROM Size: 2000 x 8 – μCOM-43
1000 x 8 – μCOM-44
1000 x 8 – μCOM-45
640 x 8
- Choice of RAM Size: 96 x 4 – μCOM-43
64 x 4 – μCOM-44
32 x 4 – μCOM-45
- Choice of I/O Power: 35 lines – μCOM-43
35 lines – μCOM-44
21 lines – μCOM-45
- All Capable of Single Bit Manipulation and 4-Bit Parallel Processing.
- Interrupt Capability
- On-Chip Clock Generator
- Open Drain Outputs
- Choice of PMOS or CMOS Technology, Both Requiring Single Supplies
- Available in 42 Pin or 28 Pin Plastic Dual-in-Line Packages

BLOCK DIAGRAMS

μCOM-44

μCOM-45

FUNCTIONAL DESCRIPTION

Program Counter

The 11-bit program counter (10-bit for μCOM-44/45) is organized as a 3-bit register (2-bit for μCOM-44/45) and an 8-bit binary up-counter (lower eight bits). The contents of the upper register specify one of the fields of the ROM. The 8-bit binary counter is divided so that the contents of the higher two bits specify one of four pages in a field and the lower six bits specify one of 64 addresses in a page. The contents of the lower eight bits of the program counter (8-bit binary up-counter) are simply incremented to execute the instructions sequentially. In a field, a page is automatically extended to the next one and four pages (256 bytes) are automatically executed.

Stack Register

The stack register is a last-in-first-out (LIFO) push down stack register organized as 3 words x 11 bits (1 word x 10 bits for μCOM-44/45). This register is used to save the contents of the program counter (return address) when a subroutine is called or an interrupt is acknowledged.

ROM (Read-Only Memory)

The user's application program is stored in the 8-bit wide mask programmable read-only memory (ROM). The ROM is organized into fields and pages. The 2000 word ROM of the μCOM-43 has eight fields, the 1000 word ROM of the μCOM-44/45 has four fields and the 640 word ROM of the low-end μCOM-45 has two fields. Each field is divided into four pages of 64 words each, and each word consists of eight bits.

©IC MASTER 1979

FUNCTIONAL DESCRIPTION (CONT.)

RAM (Data Memory)

The RAM is organized in a multi-row by 16 column configuration. It is addressed by a data pointer of which the higher bits (DPH) address the row and the lower bits (DPL) address the column. The exact RAM size for each device is shown below.

	RAM	ROW/COLUMN ORGANIZATION	DPH	DPL
μCOM-43	96 x 4	6 x 16	3	4
μCOM-44	64 x 4	4 x 16	2	4
μCOM-45	32 x 4	2 x 16	1	4

Internal Registers

The ALU (Arithmetic Logic Unit) and the ACC (Accumulator) form the heart of the μCOM-43 Family microcomputer system. The ALU performs arithmetic and logical operations and tests for operation results. The result of an operation by the ALU is stored in the ACC and in the carry F/F. The ACC is a 4-bit register which stores ALU results and other data to be processed. The carry F/F is a single bit flip-flop which indicates when a carry bit is generated during addition.

Flag Register (μCOM-43 Only)

A 4-bit word in the RAM can be specifically used as a software controlled general purpose flag register. The individual flag bits can be set or reset and tested for either a 1 or a 0. This can be done directly without modifying the RAM data pointer.

Working Registers (μCOM-43 Only)

There are six words in RAM that can be used as 4-bit general purpose working registers. These registers can be directly manipulated without modification of the data pointer and are used for data transfer and exchange between the data pointer and the working register, and between the ACC and the working register.

Programmable Interval Timer (μCOM-43 Only)

The μCOM-43 contains a software programmable interval timer composed of a 6-bit polynomial counter and a 6-bit programmable binary counter.

The initial setting of the timer is done using the timer set instruction STM, with the timer starting to count at the end of the STM instruction execution. The STM instruction contains six binary bits of immediate data which is loaded in the 6-bit programmable binary counter upon STM instruction execution. By varying the 6-bit immediate data, one of 64 time intervals can be programmed.

I/O Ports

The μCOM-43/44 have 35 input/output ports (μCOM-45 has 21) for communication with and control of the external world. These ports are organized into nine input/output ports (A to I). Eight ports (A to H) are composed of four bits each and the last port (I) is composed of three bits.

Input Ports	(4 bits each): A, B ①
Input/Output Ports	(4 bits each): C, D
Output Ports	(4 bits each): E, F, G ②, H ①
Output Ports	(3 bits): I ①

Notes: ① Not on μCOM-45.

② G Port on μCOM-45 is a single line.

©IC MASTER 1979

FUNCTIONAL DESCRIPTION (CONT.)

In order to provide flexible and efficient use of these I/O ports, a variety of input/output instructions are provided which enable single bit set/reset, single bit test and conditional skip, 4-bit parallel input/output and 8-bit immediate parallel output. The I/O instructions are divided into two types, the ones dedicated to specific ports and the ones that use the 4-bit data in the DPL to select a desired port. The former include such instructions as IA and OE that specifically access port A and E, respectively. The latter require that a 4-bit code assigned to the desired port be loaded into the DPL using data pointer manipulation instructions prior to I/O instruction execution.

INSTRUCTION SET

The μCOM-43 has an 80 instruction set. The μCOM-44/45 have a 58 instruction subset of the μCOM-43. The majority of the 22 instruction difference is related to added hardware features of the μCOM-43. The instruction set is summarized below.

MNEMONIC	BYTES	CYCLES	DESCRIPTION	CONDITION FOR SKIP

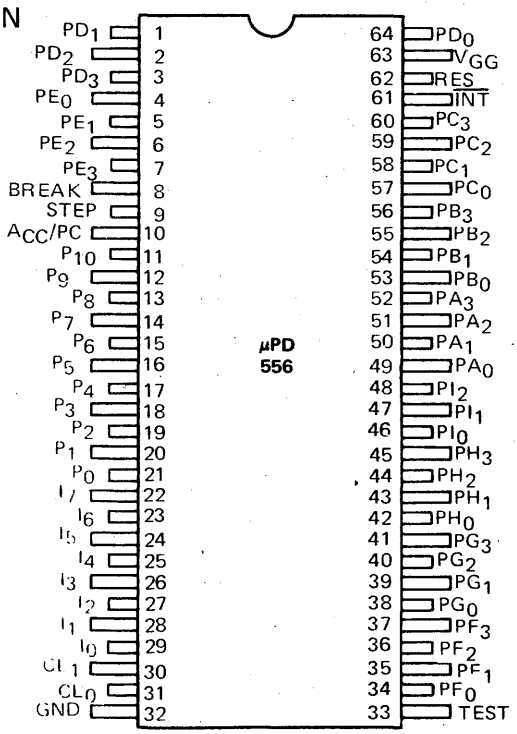
EVACHIP-43

DESCRIPTION



The μPD556 is an evaluation chip for the μCOM-43/44/45 single chip microcomputers. Designed to be used for both hardware and software debugging, the EVACHIP-43 is functionally equivalent to the μCOM-43, except that it does not contain on-chip ROM. Instead, it is able to address external memory. In addition, in order to facilitate debugging, the μPD556 is capable of displaying the contents of the internal accumulator and data pointer and of being single stepped.

When the μPD556 is being used to evaluate μCOM-44/45 designs, the external memory capacity should be restricted to that of the respective on-chip ROM and the instructions should be restricted to the 58 comprising the μCOM-44/45 instruction set.

FEATURES

- 4-bit Parallel Processor
- Full 80 Instruction Set of μCOM-43
- 10 μs Instruction Cycle
- Capable of addressing 2K x 8-bits of external program memory
- Single step capability
- Full Functionality of μCOM-43
- Single supply: -10V PMOS Technology
- Available in a 64-pin Ceramic Quad-in-Line Package

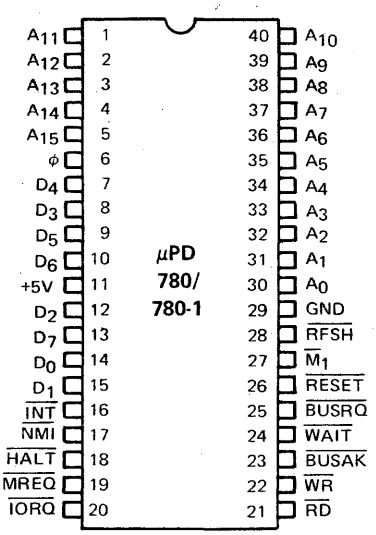
8-BIT N-CHANNEL MICROPROCESSOR COMPLETELY Z80™ COMPATIBLE

DESCRIPTION

The μPD780 and μPD780-1 processors are single chip microprocessors developed from third generation technology. Their increased computational power produces higher system through-put and more efficient memory utilization, surpassing that of any second generation microprocessor. The single voltage requirement of the μPD780 and μPD780-1 processors makes it easy to implement them into a system. All output signals are fully decoded and timed to either standard memory or peripheral circuits. An N-channel, ion implanted, silicon gate MOS process is utilized in implementing the circuit.

The block diagram shows the functions of the processor and details the internal register structure. The structure contains 26 bytes of Read/Write (R/W) memory available to the programmer. Included in the registers are two sets of six general purpose registers, which may be used as 8-bit registers individually, or as 16-bit register pairs. Also included are two sets of accumulator and flag registers.



Through a group of exchange instructions the programmer has access to either set of main or alternate registers. The alternate register permits foreground/background mode of operation, or may be used for fast interrupt response. A 16-bit stack pointer is also included in each processor, simplifying implementation of multiple level interrupts, permitting unlimited subroutine nesting, and simplifying many types of data handling.

The two 16-bit index registers simplify implementation of relocatable code and manipulation of tabular data. The Refresh register will automatically refresh external dynamic memories. A powerful interrupt response mode will use the I register to form the upper 8-bits of a pointer to an interrupt service address table, while the interrupting apparatus supplies the lower 8-bits of the pointer. An indirect call will then be made to service this address.

FEATURES

- Single Chip, N-Channel Silicon Gate Processor
- 158 Instructions — Including all 78 of the 8080A Instructions, Permitting Total Software Compatibility
- New 4-, 8-, and 16-Bit Operations Featuring Useful Addressing Modes such as Indexed, Bit and Relative
- 17 Internal Registers
- Three Modes of Rapid Interrupt Response, and One Non-Maskable Interrupt
- Directly Connects Standard Speed Dynamic or Static Memories, with Minimum Support Circuitry
- Single-Phase +5 Volt Clock and 5 VDC Supply
- TTL Compatibility
- Automatic Dynamic RAM Refresh Circuitry
- Available in Plastic Package

BLOCK DIAGRAM

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
1-5, 30-40	A_0-A_{15}	Address Bus	3-State Output, active high. Pins A_0-A_{15} constitute a 16-bit address bus, which provides the address for memory and I/O device data exchanges. Memory capacity 65,536 bytes. A_0-A_7 is also needed as refresh cycle.
7-10, 12-15	D_0-D_7	Data Bus	3-State input/output, active high. Pins D_0-D_7 compose an 8-bit, bidirectional data bus, used for data exchanges with memory and I/O devices.
27	$\overline{M_1}$	Machine Cycle One	Output, active low. $\overline{M_1}$ indicates that the machine cycle in operation is the op code fetch cycle of an instruction execution.
19	$\overline{MREQ}$	Memory Request	3-State output, active low. $\overline{MREQ}$ indicates that a valid address for a memory read or write operation is held in the address.
20	$\overline{IORQ}$	Input/Output Request	3-State output, active low. The I/O request signal indicates that the lower half of the address bus holds a valid address for an I/O read or write operation. The $\overline{IORQ}$ signal is also used to acknowledge an interrupt command, indicating that an interrupt response vector can be placed on the data bus.
21	$\overline{RD}$	Memory Read	3-State output, active low. $\overline{RD}$ indicates that the processor is requesting data from memory or an I/O device. The memory or I/O device being addressed should use this signal to gate data onto the data bus.

PIN IDENTIFICATION (CONT.)

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
22	$\overline{WR}$	Memory Write	3-State output, active low. The memory write signal indicates that the processor data bus is holding valid data to be stored in the addressed, memory or I/O device.
28	$\overline{RFSH}$	Refresh	Output, active low. $\overline{RFSH}$ indicates that a refresh address for dynamic memories is being held in the lower 7-bits of the address bus. The $\overline{MREQ}$ signal should be used to implement a refresh read to all dynamic memories.
18	$\overline{HALT}$	Halt State	Output, active low. $\overline{HALT}$ indicates that the processor has executed a HALT software instruction, and will not resume operation until either a non-maskable or a maskable (with mask enabled) interrupt has been implemented. The processor will execute NOP's while halted, to maintain memory refresh activity.
24	$\overline{WAIT}$	Wait	Input, active low. $\overline{WAIT}$ indicates to the processor that the memory or I/O devices being addressed are not ready for a data transfer. As long as this signal is active, the processor will reenter wait states.
16	$\overline{INT}$	Interrupt Request	Input, active low. The $\overline{INT}$ signal is produced by I/O devices. The request will be honored upon completion of the current instruction, if the interrupt enable flip-flop (IFF) is enabled by the internal software. There are three modes of interrupt response. Mode 0 is identical to 8080 interrupt response mode. The Mode 1 response is a restart location at 0038_H. Mode 2 is for simple vectoring to an interrupt service routine anywhere in memory.
17	$\overline{NMI}$	Non-Maskable Interrupt	Input, active low. The non-maskable interrupt has a higher priority than $\overline{INT}$. It is always acknowledged at the end of the current instruction, regardless of the status of the interrupt enable flip-flop. When the $\overline{NMI}$ signal is given, the μPD780 processor automatically restarts to location 0066_H.
26	$\overline{RESET}$	Reset	Input, active low. The $\overline{RESET}$ signal causes the processor to reset the interrupt enable flip-flop (IFF), clear PC and I and R registers, and set interrupt to 8080A mode. During the reset time, the address bus and data bus go to a state of high impedance, and all control output signals become inactive, after which processing continues at 0000H.
25	$\overline{BUSRQ}$	Bus Request	Input, active low. $\overline{BUSRQ}$ has a higher priority than $\overline{NMI}$, and is always honored at the end of the current machine cycle. It is used to allow other devices to take control over the processor address bus, data bus signals; by requesting that they go to a state of high impedance.
23	$\overline{BUSAK}$	Bus Acknowledge	Output, active low. $\overline{BUSAK}$ is used to inform the requesting device that the processor address bus, data bus and 3-state control bus signals have entered a state of high impedance, and the external device can now take control of these signals.

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	0°C to +70°C
Storage Temperature	-65°C to +150°C
Voltage on any Pin	-0.3 to +7 Volts ①
Power Dissipation	1.5W

Note: ① With Respect to Ground.

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

*T_a = 25°C

DC CHARACTERISTICS

T_a = 0°C to +70°C; V_{CC} = +5V ± 5% unless otherwise specified.

PARAMETER		SYMBOL	LIMITS MIN	LIMITS TYP	LIMITS MAX	UNIT	TEST CONDITIONS

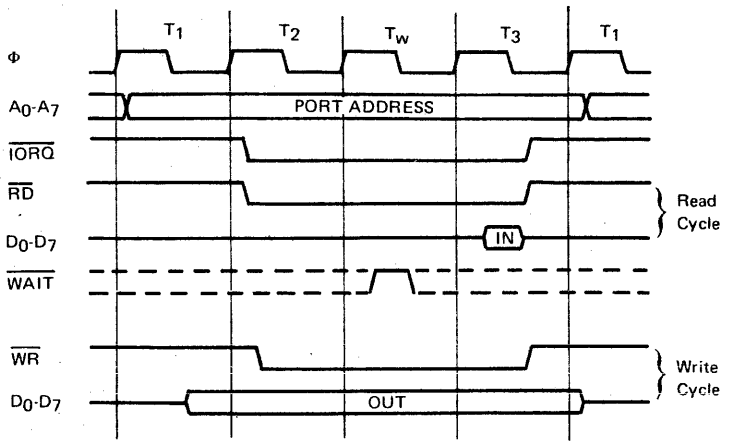
Instruction Op Code Fetch

The contents of the program counter (PC) are placed on the address bus at the start of the cycle. $\overline{MREQ}$ goes active one-half clock cycle later, and the falling edge of this signal can be used directly as a chip enable to dynamic memories. The memory data should be enabled onto the processor data bus when $\overline{RD}$ goes active. The processor takes data with the rising edge of the clock state T_3. The processor internally decodes and executes the instruction, while clock states T_3 and T_4 of the fetch cycle are used to refresh dynamic memories. The refresh control signal $\overline{RFSH}$ indicates that a refresh read should be done to all dynamic memories.

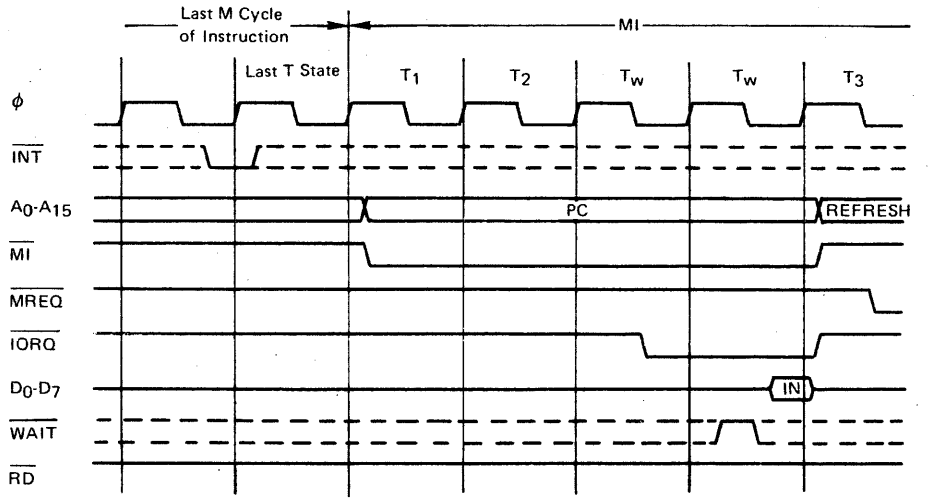
Memory Read or Write Cycles

This diagram illustrates the timing of memory read or write cycles other than an op code fetch (M_1 cycle). The function of the $\overline{MREQ}$ and $\overline{RD}$ signals is exactly the same as in the op code fetch cycle. When a memory write cycle is implemented, the $\overline{MREQ}$ becomes active and is used directly as a chip enable for dynamic memories, when the address bus is stable. The $\overline{WR}$ line is used directly as a R/W pulse to any type of semiconductor memory, and is active when data on the data bus is stable.



©IC MASTER 1979

TIMING WAVEFORMS (CONT.)



Input or Output Cycles

This illustrates the timing for an I/O read or I/O write operation. A single wait-state (T_W) is automatically inserted in I/O operations to allow sufficient time for an I/O port to decode its address and activate the $\overline{WAIT}$ line, if necessary.

Interrupt Request/Acknowledge Cycle

The processor samples the interrupt signal with the rising edge of the last clock at the end of any instruction. A special M_1 cycle is started when an interrupt is accepted. During the M_1 cycle, the $\overline{IORQ}$ (instead of $\overline{MREQ}$) signal becomes active, indicating that the interrupting device can put an 8-bit vector on the data bus. Two wait states (T_W) are automatically added to this cycle. This makes it easy to implement a ripple priority interrupt scheme.

INSTRUCTION SET

The following summary shows the assembly language mnemonic and the symbolic operation performed by the instructions of the μPD780 and μPD780-1 processors. The instructions are divided into 16 categories:

Miscellaneous Group	8-Bit Loads
Rotates and Shifts	16-Bit Loads
Bit Set, Reset and Test	Exchanges
Input and Output	Memory Block Moves
Jumps	Memory Block Searches
Calls	8-Bit Arithmetic and Logic
Restarts	16-Bit Arithmetic
Returns	General Purpose Accumulator and Flag Operations

The addressing Modes include combinations of the following:

Indexed	Immediate
Register	Immediate Extended
Implied	Modified Page Zero
Register Indirect	Relative
Bit	Extended

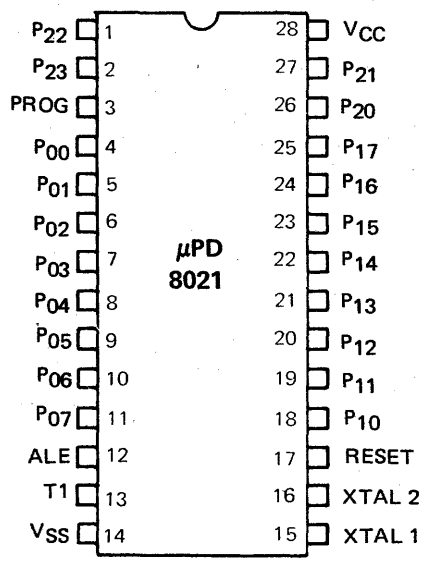
SINGLE CHIP 8-BIT MICROCOMPUTER



DESCRIPTION

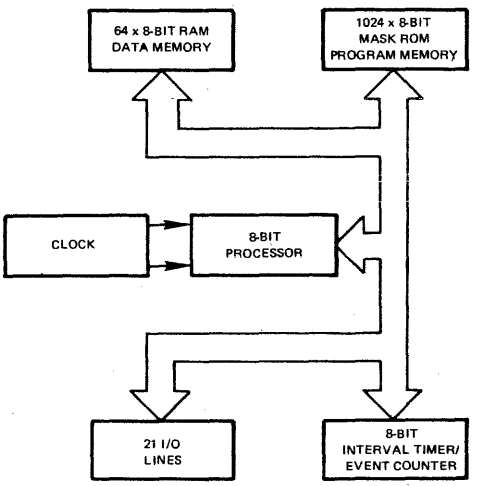
The NEC μPD8021 is a stand alone 8-bit parallel microcomputer incorporating the following features usually found in external peripherals. The μPD8021 contains: 1K x 8-bits of mask ROM program memory, 64 x 8 bits of RAM data memory, 21 I/O lines, an 8-bit interval timer/event counter, and internal clock circuitry.

FEATURES

- 8-Bit Processor, ROM, RAM, I/O, Timer/Counter
- Single +5V Supply (+4.5V to +6.5V)
- NMOS Silicon Gate Technology
- 10 μs Cycle Time
- All Instructions 1 or 2 Cycles
- Instructions are Subset of μPD8048/8748/8035
- High Current Drive Capability — 2 I/O Pins
- Clock Generation Using Single Resistor or Inductor
- Zero-Cross Detection Capability
- Expandable I/O Using μPD8243's
- Available in 28 Pin Plastic Package

PIN CONFIGURATION

©IC MASTER 1979



μPD8021

FUNCTIONAL DESCRIPTION

The NEC μPD8021 is a single component, 8-bit, parallel microprocessor using N-channel silicon gate MOS technology. The self-contained 1K x 8-bit ROM, 64 x 8-bit RAM, 8-bit timer/counter, and clock circuitry allow the μPD8021 to operate as a single-chip microcomputer in applications ranging from controllers to arithmetic processors.

The instruction set, a subset of the μPD8048/8748/8035, is optimum for high-volume, low cost applications where I/O flexibility and instruction set power are required. The μPD8021 instruction set is comprised mostly of single-byte instructions with no instructions over two bytes.

BLOCK DIAGRAM

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature . . . . . 0°C to +70°C
Storage Temperature (Ceramic Package) . . . . . -65°C to +150°C
(Plastic Package) . . . . . -65°C to +125°C
Voltage on Any Pin . . . . . -0.5 to +7 Volts ①
Power Dissipation. . . . . 1 Watt

Note: ① With Respect to Ground.

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

*T_a = 25°C

DC CHARACTERISTICS

T_a = 0°C to +70°C; V_{CC} = +5.5V ± 1V; V_{SS} = 0V

PARAMETER	SYMBOL	LIMITS MIN	LIMITS TYP	LIMITS MAX	UNIT	TEST CONDITIONS
Input Low Voltage (All Except XTAL 1, XTAL 2)	V_{IL}	-0.5		+ 0.8	V	
Input High Voltage (All Except XTAL 1, XTAL 2)	V_{IH}	2.0		V_{CC}	V	V_{CC} = 5.0V ± 10%
Input High Voltage (All Except XTAL 1, XTAL 2)	V_{IH1}	3.0		V_{CC}	V	V_{CC} = 5.5V ± 1V
Output Low Voltage	V_{OL}			0.45	V	I_{OL} = 1.6 mA
Output Low Voltage (P_{10}, P_{11})	V_{OL1}			2.5	V	I_{OL} = 7 mA

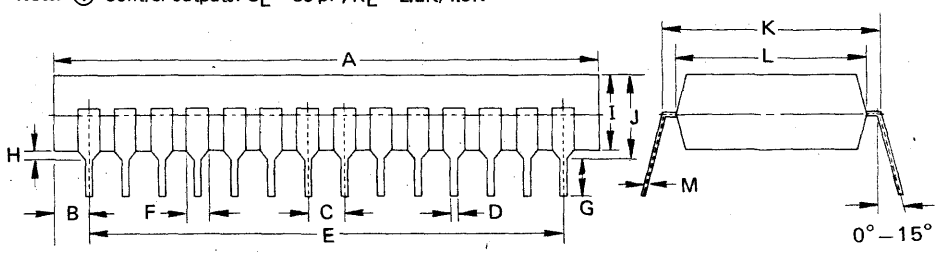
PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	FUNCTION
1-2, 26-27	P_{20}-P_{23} (Port 2)	P_{20}-P_{23} comprise the 4-bit bi-directional I/O port which is also used as the expander bus for the μPD8243.
3	PROG	PROG is the output strobe pin for the μPD8243.
4-11	P_{00}-P_{07} (Port 0)	One of the two 8-bit quasi bi-directional I/O ports.
12	ALE	Address Latch Enable output (active-high). Occurring once every 30 input clock periods, ALE can be used as an output clock.
13	T1	Testable input using transfer functions JT1 and JNT1. T1 can be made the counter/timer input using the STRT CNT instruction. T1 also provides zero-cross sensing for low-frequency AC input signals.
14	V_{SS}	Processor's ground potential.
15	XTAL 1	One side of frequency source input using resistor, inductor, crystal or external source. (non-TTL compatible V_{IH}).
16	XTAL 2	The other side of frequency source input.
17	RESET	RESET initializes the processor, setting program counter to zero and clearing status flip-flops.
18-25	P_{10}-P_{17} (Port 1)	The second of two 8-bit quasi bi-directional I/O ports.
28	V_{CC}	+5V power supply input.



AC CHARACTERISTICS

$T_a = 0°C$ to $+70°C$; $V_{CC} = 5.5V \pm 1V$; $V_{SS} = 0V$

PARAMETER	SYMBOL	LIMITS MIN	LIMITS TYP	LIMITS MAX	UNIT	TEST CONDITIONS
Cycle Time	T_{CY}	10.0		50.0	μs	3 MHz XTAL = 10 μs ①

NOP		No Operation performed.	0	0	0	0	0	0	0	0	1	1	

Notes: ① Instruction Code Designations r and p form the binary representation of the Registers and Ports involved.
② The dot under the appropriate flag bit indicates that its content is subject to change by the instruction it appears in.
③ References to the address and data are specified in bytes 2 and/or 1 of the instruction.
④ Numerical Subscripts appearing in the FUNCTION column reference the specific bits affected.

Symbol Definitions

SYMBOL	DESCRIPTION
A	The Accumulator
addr	Program Memory Address (12 bits)
C	Carry Flag
CLK	Clock Signal
CNT	Event Counter
D	Nibble Designator (4 bits)
data	Number or Expression (8 bits)
P	"In-Page" Operation Designator
P_p	Port Designator (p = 1, 2 or 4 - 7)
Rr	Register Designator (r = 0, 1 or 0 - 7)

SYMBOL	DESCRIPTION
T	Timer
T_1	Testable Flag 1
X	External RAM
=	Prefix for Immediate Data
@	Prefix for Indirect Address
$	Program Counter's Current Value
(x)	Contents of External RAM Location
((x))	Contents of Memory Location Addressed by the Contents of External RAM Location
←	Replaced By

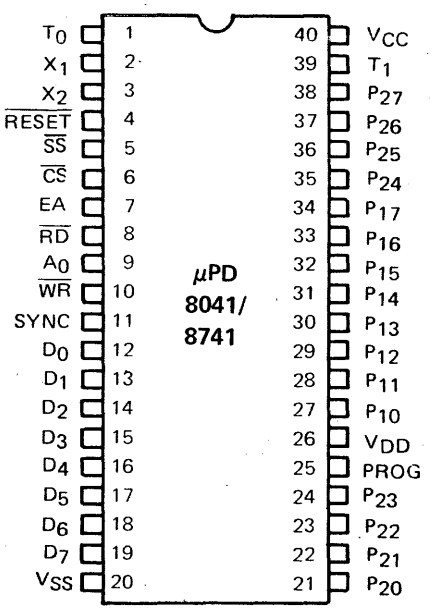
UNIVERSAL PROGRAMMABLE PERIPHERAL INTERFACE 8-BIT MICROCOMPUTERS

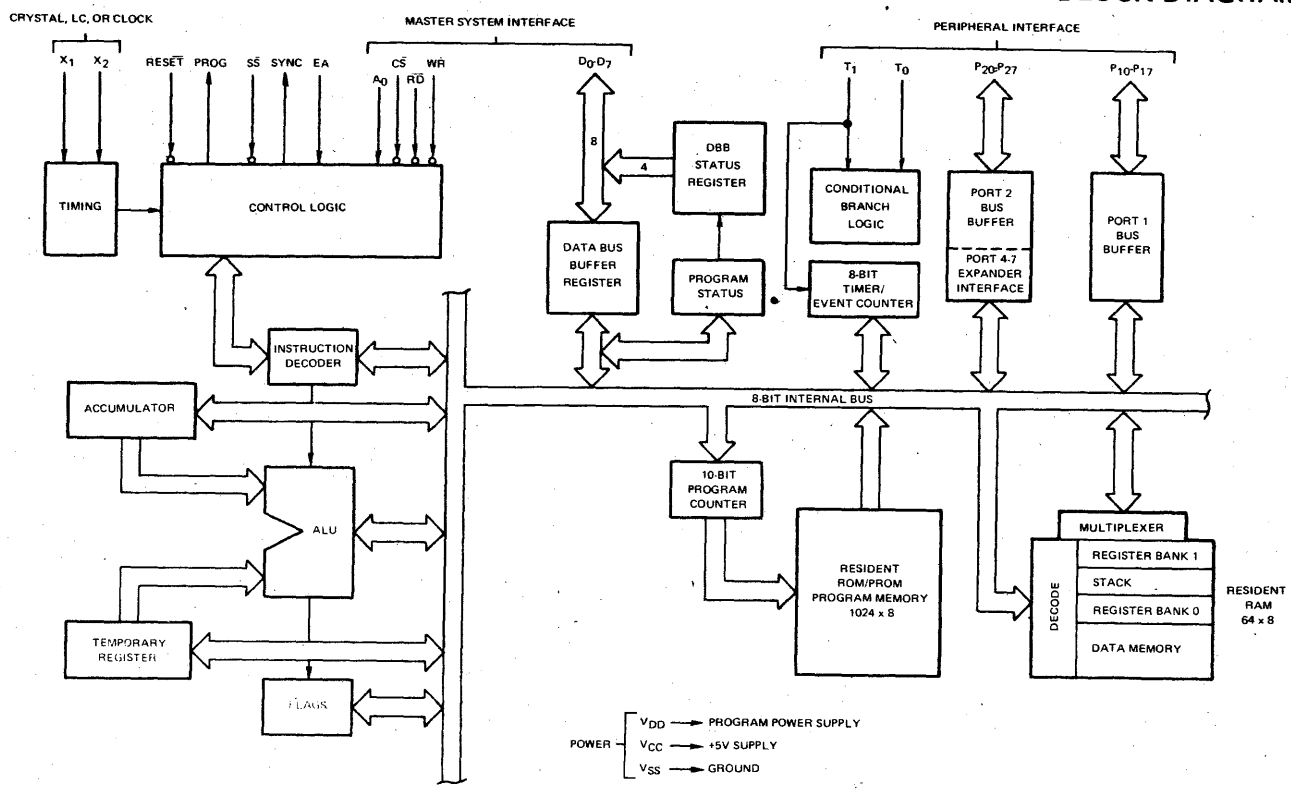


DESCRIPTION

The μPD8041 and μPD8741 are 8-bit single component microcomputers which function as general purpose programmable interfaces between the host processor and many various peripheral devices. The μPD8041 and μPD8741 differ only in their internal program memories. The μPD8041 contains 1024 x 8 bytes of mask ROM, while the μPD8741 contains 1024 x 8 bytes of UV EPROM. Some of the features offered by both devices include 64 x 8 bytes of RAM data memory, an 8-bit programmable counter/timer, 16 TTL compatible I/O lines, and two test inputs.

FEATURES

- Fully Compatible with 8080A, 8085A, and 8048 Families
- Single +5V Supply
- Fully Compatible ROM and EPROM Versions
- 1024 x 8 ROM/EPROM, 64 x 8 RAM
- 18 Programmable I/O Lines
- Expandable I/O
- Two Single Level Interrupts
- Single Package: 8-Bit Processor, ROM, RAM, Timer, I/O and Clock
- Asynchronous Data Register for Master Processor Interface
- Available in Both Plastic and Ceramic 40-Pin Packages



PIN CONFIGURATION

*All data pertaining to the μPD8741 is preliminary.

©IC MASTER 1979

BLOCK DIAGRAM

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	0°C to +70°C
Storage Temperature (Ceramic Package)	−65°C to +150°C
Storage Temperature (Plastic Package)	−65°C to +125°C
Voltage on Any Pin	−0.5 to +7 Volts ①
Power Dissipation	1.5 Watt

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note: ① With respect to ground.

*T_a = 25°C

DC CHARACTERISTICS

T_a = 0°C to +70°C; $V_{DD} = V_{CC}$ = +5V ± 5%; V_{SS} = 0V

PARAMETER	SYMBOL	LIMITS MIN	LIMITS TYP	LIMITS MAX	UNIT	TEST CONDITIONS
Input Low Voltage (All except X_1 and X_2)	V_{IL}	−0.5		+0.8	V	
Input High Voltage (All except X_1, X_2, $\overline{RESET}$)	V_{IH1}	2.0		V_{CC}	V	
Input High Voltage (X_1, X_2, $\overline{RESET}$)	V_{IH2}	3.0		V_{CC}	V	
Output Low Voltage (D_0-D_7, SYNC)	V_{OL1}			0.45	V	I_{OL} = 2.0 mA
Output Low Voltage (All other outputs except PROG)	V_{OL2}			0.45	V	I_{OL} = 1.6 mA
Output Low Voltage (PROG)	V_{OL3}			0.45	V	I_{OL} = 1.0 mA
Output High Voltage (D_0-D_7)	V_{OH1}	2.4			V	I_{OH} = −400 μA
Output High Voltage (All other outputs)	V_{OH2}	2.4			V	I_{OH} = −50 μA
Input Leakage Current (T_0, T_1, $\overline{RD}$, $\overline{WR}$, $\overline{CS}$, EA, A_0)	I_{IL}			±10	μA	$V_{SS} < V_{IN} < V_{CC}$
Output Leakage Current (D_0-D_7; High Z State)	I_{OL}			±10	μA	V_{SS} + 0.45 < $V_{IN} < V_{CC}$
V_{DD} Supply Current	I_{DD}			25	mA	
Total Supply Current	$I_{CC} + I_{DD}$			135	mA	
Low Input Source Current (P_{10}-P_{17}; P_{20}-P_{27})	I_{LI1}			0.4	mA	V_{IL} = 0.8V
Low Input Source Current (SS; $\overline{RESET}$)	I_{LI2}			0.2	mA	V_{IL} = 0.8V

©IC MASTER 1979

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	FUNCTION
1,39	T_0, T_1	Testable input pins using conditional transfer functions JT0, JNT0, JT1, JNT1. T_1 can be made the counter/timer input using the STRT CNT instruction. The PROM programming and verification on the 8741 uses T_0.
2	X_1	One side of the crystal input for external oscillator or frequency source.
3	X_2	The other side of the crystal input.
4	$\overline{RESET}$	Active-low input for processor initialization. $\overline{RESET}$ is also used for PROM programming, verification, and power down.
5	$\overline{SS}$	Single Step input (active-low). $\overline{SS}$ together with SYNC output allows the μPD8741 to "single-step" through each instruction in program memory.
6	$\overline{CS}$	Chip Select input (active-low). $\overline{CS}$ is used to select the appropriate μPD8041/8741 on a common data bus.
7	EA	External Access input (active-h[illegible]). A logic "1" at this input commands the μPD8041/8741 to perform all program memory fetches from external memory.
8	$\overline{RD}$	Read strobe input (active-low). $\overline{RD}$ will pulse low when the master processor reads data and status words from the DATA BUS BUFFER or Status Register.
9	A_0	Address input which the master processor uses to indicate if a byte transfer is a command or data.
10	$\overline{WR}$	Write strobe input (active-low). $\overline{WR}$ will pulse low when the master processor writes data or status words to the DATA BUS BUFFER or Status Register.
11	SYNC	The SYNC output pulses once for each μPD8041/8741 instruction cycle. It can function as a strobe for external circuitry. SYNC can also be used together with $\overline{SS}$ to "single-step" through each instruction in program memory.
12-19	D_0-D_7 BUS	The 8-bit, bi-directional, tri-state DATA BUS BUFFER lines by which the μPD8041/8741 interfaces to the 8-bit master system data bus.
20	V_{SS}	Processor's ground potential.
21-24, 35-38	P_{20}-P_{27}	PORT 2 is the second of two 8-bit, quasi-bi-directional I/O ports. P_{20}-P_{23} contain the four most significant bits of the program counter during external memory fetches. P_{20}-P_{23} also serve as a 4-bit I/O bus for the μPD8243, INPUT/OUTPUT EXPANDER.
25	PROG	Program Pulse. PROG is used in programming the μPD8741. It is also used as an output strobe for the μPD8243.
26	V_{DD}	V_{DD} is the programming supply voltage for programming the μPD8741. It is +5V for normal operation of the μPD8041/8741. V_{DD} is also the Low Power Standby input for the ROM version.
27-34	P_{10}-P_{17}	PORT 1 is the first of two 8-bit quasi-bi-directional I/O ports.
40	V_{CC}	Primary power supply. V_{CC} must be +5V for programming and operation of the μPD8741 and for the operation of the μPD8041.

Notes: ① Instruction Code Designations r and p form the binary representation of the Registers and Ports involved.

② The dot under the appropriate flag bit indicates that its content is subject to change by the instruction it appears in.

③ References to the address and data are specified in bytes 2 and/or 1 of the instruction.

④ Numerical Subscripts appearing in the FUNCTION column reference the specific bits affected.

Symbol Definitions:

SYMBOL	DESCRIPTION
A	The Accumulator
AC	The Auxiliary Carry Flag
addr	Program Memory Address (12 bits)
Bb	Bit Designator (b = 0 – 7)
BS	The Bank Switch
BUS	The BUS Port
C	Carry Flag
CLK	Clock Signal
CNT	Event Counter
D	Nibble Designator (4 bits)
data	Number or Expression (8 bits)
DBF	Memory Bank Flip-Flop
F_0, F_1	Flags 0, 1
I	Interrupt
P	"In-Page" Operation Designator
IBF	Input Buffer Full Flag

SYMBOL	DESCRIPTION
P_p	Port Designator (p = 1, 2 or 4 – 7)
PSW	Program Status Word
Rr	Register Designator (r = 0, 1 or 0 – 7)
SP	Stack Pointer
T	Timer
TF	Timer Flag
T_0, T_1	Testable Flags 0, 1
X	External RAM
#	Prefix for Immediate Data
@	Prefix for Indirect Address
$	Program Counter's Current Value
(x)	Contents of External RAM Location
((x))	Contents of Memory Location Addressed by the Contents of External RAM Location.
←	Replaced By
OBF	Output Buffer Full
DBB	Data Bus Buffer

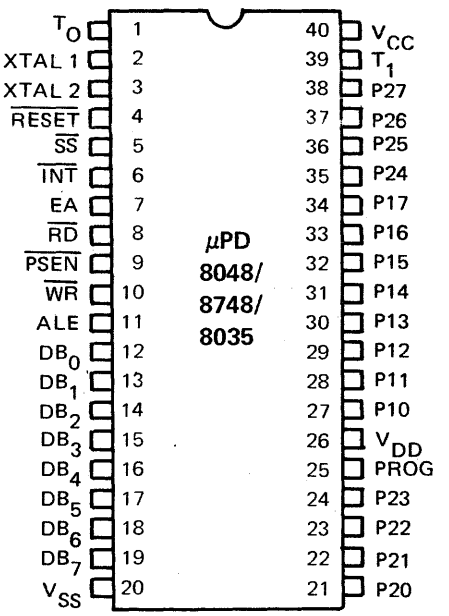
μPD8048
μPD8748*
μPD8035

μPD8048 FAMILY OF SINGLE CHIP 8-BIT MICROCOMPUTERS



DESCRIPTION

The μPD8048 family of single chip 8-bit microcomputers is comprised of the μPD8048, μPD8748 and μPD8035. The processors in this family differ only in their internal program memory options: the μPD8048 with 1K x 8 bytes of mask ROM, the μPD8748 with 1K x 8 bytes of UV erasable EPROM and the μPD8035 with external memory.

FEATURES

- Fully Compatible With Industry Standard 8048/8748/8035
- NMOS Silicon Gate Technology Requiring a Single +5V Supply
- 2.5 μs Cycle Time. All Instruction 1 or 2 Bytes
- Interval Timer/Event Counter
- 64 x 8 Byte RAM Data Memory
- Single Level Interrupt
- 96 Instructions: 70% Single Byte
- 27 I/O Lines
- Internal Clock Generator
- 8 Level Stack
- Compatible With 8080A/8085A Peripherals
- Available in Both Ceramic and Plastic 40 Pin Packages

PIN CONFIGURATION

*All data pertaining to the μPD8748 is preliminary.

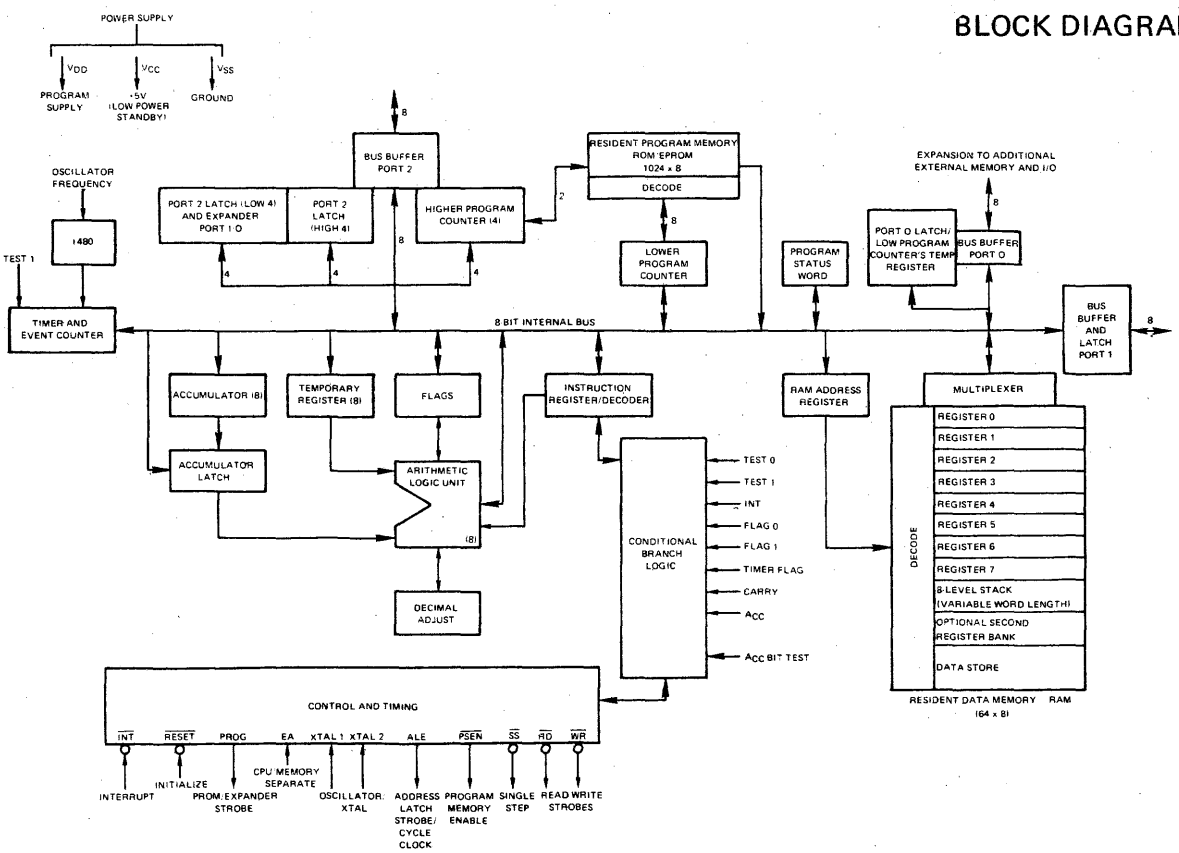
©IC MASTER 1979

μPD8048 FAMILY

FUNCTIONAL DESCRIPTION

The NEC μPD8048, μPD8748 and μPD8035 are single component, 8-bit, parallel microprocessors using N-channel silicon gate MOS technology. The μPD8048/8748/8035 efficiently function in control as well as arithmetic applications. The flexibility of the instruction set allows for the direct set and reset of individual data bits within the accumulator and the I/O port structure. Standard logic function implementation is facilitated by the large variety of branch and table look-up instructions.

The μPD8048/8748/8035 instruction set is comprised of 1 and 2 byte instructions with over 70% single-byte and requiring only 1 or 2 cycles per instruction with over 50% single-cycle.



The μPD8048 series of microprocessors will function as stand alone microcomputers. Their functions can easily be expanded using standard 8080A/8085A peripherals and memories.

The μPD8048 contains the following functions usually found in external peripheral devices: 1024 x 8 bits of ROM program memory; 64 x 8 bits of RAM data memory; 27 I/O lines; an 8-bit interval timer/event counter; oscillator and clock circuitry.

The μPD8748 differs from the μPD8048 only in its 1024 x 8-bit UV erasable EPROM program memory instead of the 1024 x 8-bit ROM memory. It is useful in preproduction or prototype applications where the software design has not yet been finalized or in system designs whose quantities do not require a mask ROM.

The μPD8035 is intended for applications using external program memory only. It contains all the features of the μPD8048 except the 1024 x 8-bit internal ROM. The external program memory can be implemented using standard 8080A/8085A memory products.

BLOCK DIAGRAM

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	FUNCTION
1	T_0	Testable input using conditional transfer functions JT0 and JNT0. The internal State Clock (CLK) is available to T_0 using the ENTO CLK instruction. T_0 can also be used during programming as a testable flag.
2	XTAL 1	One side of the crystal input for external oscillator or frequency (non TTL compatible V_{IH}).
3	XTAL 2	The other side of the crystal input.
4	$\overline{RESET}$	Active low input for processor initialization. $\overline{RESET}$ is also used for PROM programming verification and power-down (non TTL compatible V_{IH}).
5	$\overline{SS}$	Single Step input (active-low). $\overline{SS}$ together with ALE allows the processor to "single-step" through each instruction in program memory.
6	$\overline{INT}$	Interrupt input (active-low). $\overline{INT}$ will start an interrupt if an enable interrupt instruction has been executed. A reset will disable the interrupt. $\overline{INT}$ can be tested by issuing a conditional jump instruction.
7	EA	External Access input (active-high). A logic "1" at this input commands the processor to perform all program memory fetches from external memory.
8	$\overline{RD}$	READ strobe output (active-low). $\overline{RD}$ will pulse low when the processor performs a BUS READ. $\overline{RD}$ will also enable data onto the processor BUS from a peripheral device and function as a READ STROBE for external DATA MEMORY.
9	$\overline{PSEN}$	Program Store Enable output (active-low). $\overline{PSEN}$ becomes active only during an external memory fetch.
10	$\overline{WR}$	WRITE strobe output (active-low). $\overline{WR}$ will pulse low when the processor performs a BUS WRITE. $\overline{WR}$ can also function as a WRITE STROBE for external DATA MEMORY.
11	ALE	Address Latch Enable output (active-high). Occurring once each cycle, the falling edge of ALE latches the address for external memory or peripherals. ALE can also be used as a clock output.
12 – 19	$D_0 - D_7$ BUS	8-bit, bidirectional port. Synchronous reads and writes can be performed on this port using $\overline{RD}$ and $\overline{WR}$ strobes. The contents of the $D_0 - D_7$ BUS can be latched in a static mode. During an external memory fetch, the $D_0 - D_7$ BUS holds the least significant bits of the program counter. $\overline{PSEN}$ controls the incoming addressed instruction. Also, for an external RAM data store instruction the $D_0 - D_7$ BUS, controlled by ALE, $\overline{RD}$ and $\overline{WR}$, contains address and data information.
20	V_{SS}	Processor's GROUND potential.
21 – 24, 35 – 38	$P_{20} - P_{27}$: PORT 2	Port 2 is the second of two 8-bit quasi-bidirectional ports. For external data memory fetches, the four most significant bits of the program counter are contained in $P_{20} - P_{23}$. Bits $P_{20} - P_{23}$ are also used as a 4-bit I/O bus for the μPD8243, INPUT/OUTPUT EXPANDER.
25	PROG	Program Pulse. A +25V pulse applied to this input is used for programming the μPD8748. PROG is also used as an output strobe for the μPD8243.
26	V_{DD}	Programming Power Supply. V_{DD} must be set to +25V for programming the μPD8748, and to +5V for the ROM and PROM versions for normal operation. V_{DD} functions as the Low Power Standby input for the μPD8048.
27 – 34	$P_{10} - P_{17}$: PORT 1	Port 1 is one of two 8-bit quasi-bidirectional ports.
39	T1	Testable input using conditional transfer functions JT1 and JNT1. T1 can be made the counter/timer input using the STRT CNT instruction.
40	V_{CC}	Primary Power Supply. V_{CC} must be +5V for programming and operation of the μPD8748, and for operation of the μPD8035 and μPD8048.

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature . . . . . 0°C to +70°C
Storage Temperature (Ceramic Package) . . . . . −65°C to +150°C
Storage Temperature (Plastic Package) . . . . . −65°C to +125°C
Voltage on Any Pin . . . . . − 0.5 to +7 Volts ①
Power Dissipation . . . . . 1.5 W

Note: ① With respect to ground.

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

*T_a = 25°C

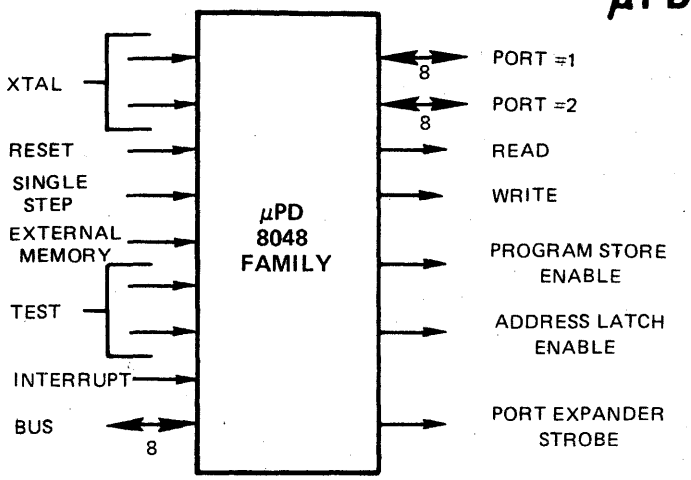
Notes: ① Instruction Code Designations r and p form the binary representation of the Registers and Ports involved.

② The dot under the appropriate flag bit indicates that its content is subject to change by the instruction it appears in.

③ References to the address and data are specified in bytes 2 and/or 1 of the instruction.

④ Numerical Subscripts appearing in the FUNCTION column reference the specific bits affected.



Symbol Definitions:

SYMBOL	DESCRIPTION
A	The Accumulator
AC	The Auxiliary Carry Flag
addr	Program Memory Address (12 bits)
Bb	Bit Designator (b = 0 – 7)
BS	The Bank Switch
BUS	The BUS Port
C	Carry Flag
CLK	Clock Signal
CNT	Event Counter
D	Nibble Designator (4 bits)
data	Number or Expression (8 bits)
DBF	Memory Bank Flip-Flop
F_0, F_1	Flags 0, 1
I	Interrupt
P	"In-Page" Operation Designator

SYMBOL	DESCRIPTION
P_p	Port Designator (p = 1, 2 or 4 – 7)
PSW	Program Status Word
Rr	Register Designator (r = 0, 1 or 0 – 7)
SP	Stack Pointer
T	Timer
TF	Timer Flag
T_0, T_1	Testable Flags 0, 1
X	External RAM
=	Prefix for Immediate Data
@	Prefix for Indirect Address
$	Program Counter's Current Value
(x)	Contents of External RAM Location
((x))	Contents of Memory Location Addressed by the Contents of External RAM Location.

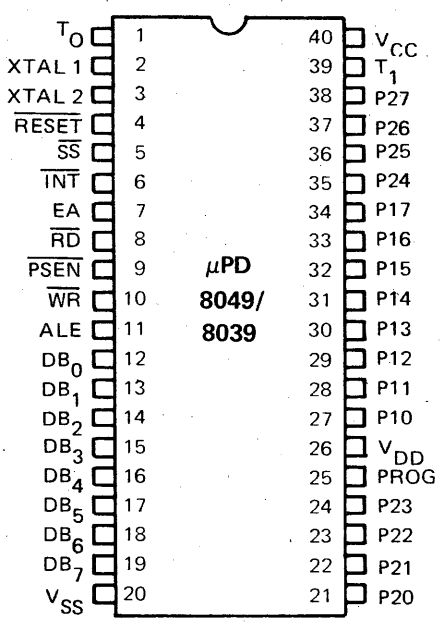
NEC

μPD8049
μPD8039

PRELIMINARY

SINGLE CHIP 8-BIT MICROCOMPUTERS



DESCRIPTION

The NEC μPD8049 and μPD8039 are single chip 8-bit microcomputers. The processors differ only in their internal program memory options: the μPD8049 with 2K x 8 bytes of mask ROM and the μPD8039 with external program memory.

FEATURES

- Fully Compatible with Industry Standard 8049/8039
- Pin Compatible with the μPD8048/8748/8035
- NMOS Silicon Gate Technology Requiring a Single +5V Supply
- 2.5 μs Cycle Time. All Instructions 1 or 2 Bytes
- Interval Timer/Event Counter
- 2K x 8 Bytes of ROM, 128 x 8 Bytes of RAM
- Single Level Interrupt
- 96 Instructions: 70 Percent Single Byte
- 27 I/O Lines
- Internal Clock Generator
- Compatible with 8080A/8085A Peripherals
- Available in Both Ceramic and Plastic 40-Pin Packages

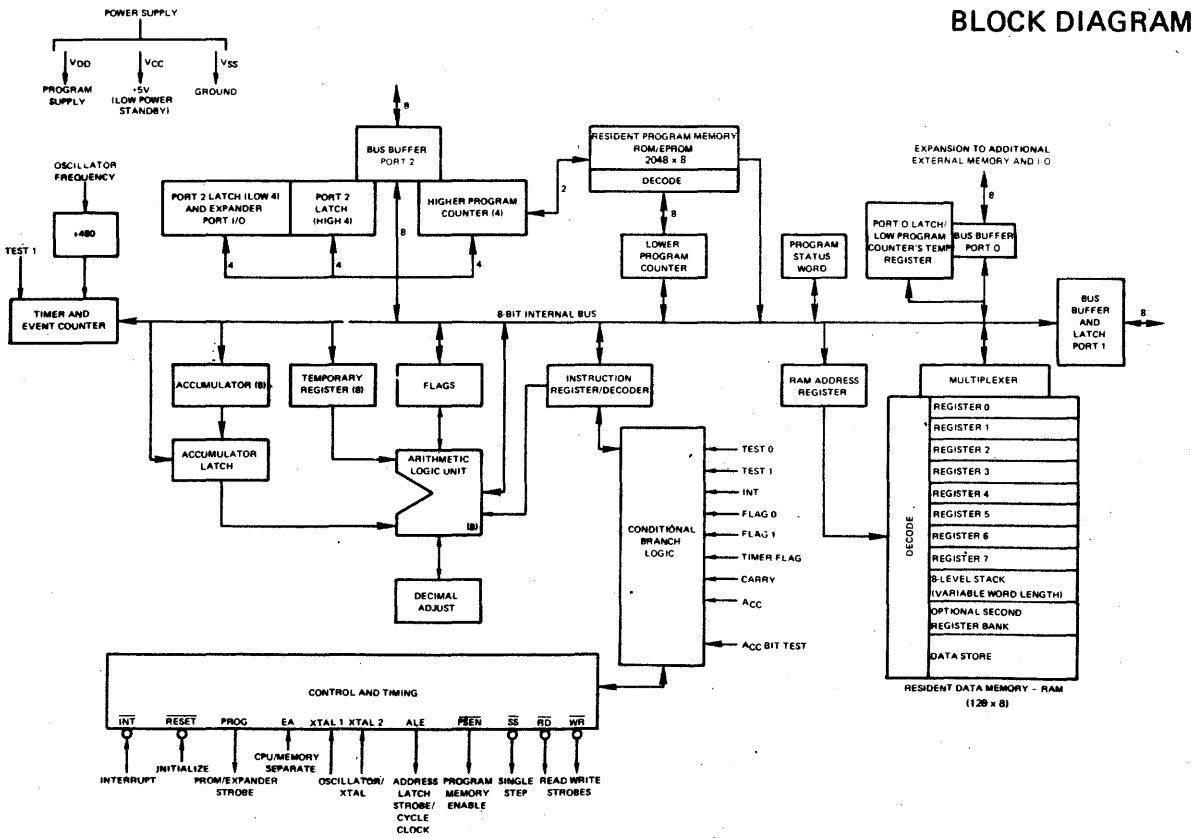
PIN CONFIGURATION

©IC MASTER 1979

μPD8049/8039

FUNCTIONAL DESCRIPTION

The NEC μPD8049 and μPD8039 are single component, 8-bit, parallel microprocessors using N-channel silicon gate MOS technology. The μPD8049 and μPD8039 efficiently function in control as well as arithmetic applications. The flexibility of the instruction set allows for the direct set and reset of individual data bits within the accumulator and the I/O port structure. Standard logic function implementation is facilitated by the large variety of branch and table look-up instructions.



The μPD8049 and μPD8039 instruction set is comprised of 1 and 2 byte instructions with over 70 percent single-byte and requiring only 1 or 2 cycles per instruction with over 50 percent single-cycle.

The μPD8049 and μPD8039 microprocessors will function as stand-alone microcomputers. Their functions can easily be expanded using standard 8080A/8085A peripherals and memories.

The μPD8049 contains the following functions usually found in external peripheral devices: 2048 x 8 bits of mask ROM program memory; 128 x 8 bits of RAM data memory; 27 I/O lines; an 8-bit interval timer/event counter; and oscillator and clock circuitry.

The μPD8039 is intended for applications using external program memory only. It contains all the features of the μPD8049 except the 2048 x 8-bit internal ROM. The external program memory can be implemented using standard 8080A/8085A memory products.

BLOCK DIAGRAM

©IC MASTER 1979

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	FUNCTION
1	T_0	Testable input using conditional transfer functions JT0 and JNT0. The internal State Clock (CLK) is available to T_0 using the ENTO CLK instruction. T_0 can also be used during programming as a testable flag.
2	XTAL 1	One side of the crystal input for external oscillator or frequency (non TTL compatible V_{IH}).
3	XTAL 2	The other side of the crystal input.
4	$\overline{RESET}$	Active low input for processor initialization. $\overline{RESET}$ is also used for PROM programming verification and power-down (non TTL compatible V_{IH}).
5	$\overline{SS}$	Single Step input (active-low). $\overline{SS}$ together with ALE allows the processor to "single-step" through each instruction in program memory.
6	$\overline{INT}$	Interrupt input (active-low). $\overline{INT}$ will start an interrupt if an enable interrupt instruction has been executed. A reset will disable the interrupt. $\overline{INT}$ can be tested by issuing a conditional jump instruction.
7	EA	External Access input (active-high). A logic "1" at this input commands the processor to perform all program memory fetches from external memory.
8	$\overline{RD}$	READ strobe output (active-low). $\overline{RD}$ will pulse low when the processor performs a BUS READ. $\overline{RD}$ will also enable data onto the processor BUS from a peripheral device and function as a READ STROBE for external DATA MEMORY.
9	$\overline{PSEN}$	Program Store Enable output (active-low). $\overline{PSEN}$ becomes active only during an external memory fetch.
10	$\overline{WR}$	WRITE strobe output (active-low). $\overline{WR}$ will pulse low when the processor performs a BUS WRITE. $\overline{WR}$ can also function as a WRITE STROBE for external DATA MEMORY.
11	ALE	Address Latch Enable output (active-high). Occurring once each cycle, the falling edge of ALE latches the address for external memory or peripherals. ALE can also be used as a clock output.
12 – 19	$D_0 - D_7$ BUS	8-bit, bidirectional port. Synchronous reads and writes can be performed on this port using $\overline{RD}$ and $\overline{WR}$ strobes. The contents of the $D_0 - D_7$ BUS can be latched in a static mode. During an external memory fetch, the $D_0 - D_7$ BUS holds the least significant bits of the program counter. PSEN controls the incoming addressed instruction. Also, for an external RAM data store instruction the $D_0 - D_7$ BUS, controlled by ALE, $\overline{RD}$ and $\overline{WR}$, contains address and data information.
20	V_{SS}	Processor's GROUND potential.
21 – 24, 35 – 38	$P_{20} - P_{27}$: PORT 2	Port 2 is the second of two 8-bit quasi-bidirectional ports. For external data memory fetches, the four most significant bits of the program counter are contained in $P_{20} - P_{23}$. Bits $P_{20} - P_{23}$ are also used as a 4-bit I/O bus for the μPD8243, INPUT/OUTPUT EXPANDER.
25	PROG	PROG is the output strobe for the μPD8243 I/O expander.
26	V_{DD}	V_{DD} is +5V for normal operation. It also functions as low power standby pin.
27 – 34	$P_{10} - P_{17}$: PORT 1	Port 1 is one of two 8-bit quasi-bidirectional ports.
39	T1	Testable input using conditional transfer functions JT1 and JNT1. T1 can be made the counter/timer input using the STRT CNT instruction.
40	V_{CC}	Primary Power supply. V_{CC} is +5V during normal operation.

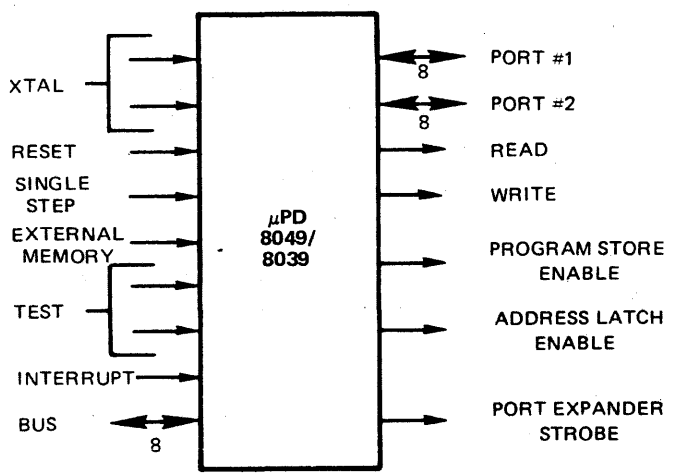
ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	0°C to +70°C
Storage Temperature (Ceramic Package)	-65°C to +150°C
Storage Temperature (Plastic Package)	-65°C to +125°C
Voltage on Any Pin	- 0.5 to +7 Volts ①
Power Dissipation	1.5 W

Note: ① With respect to ground.

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.



*T_a = 25°C

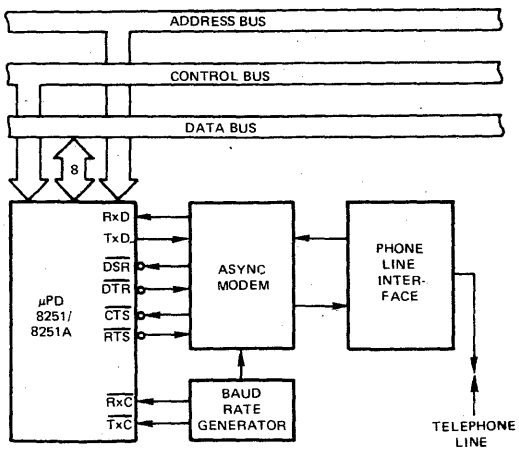
PIN IDENTIFICATION



PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
1, 2, 27, 28 5 – 8	$D_7 - D_0$	Data Bus Buffer	An 8-bit, 3-state bi-directional buffer used to interface the μPD8251 and μPD8251A to the processor data bus. Data is transmitted or received by the buffer in response to input/output or Read/Write instructions from the processor. The Data Bus Buffer also transfers Control words, Command words, and Status.
26	V_{CC}	V_{CC} Supply Voltage	+5 volt supply
4	GND	Ground	Ground
Read/Write Control Logic			This logic block accepts inputs from the processor Control Bus and generates control signals for overall USART operation. The Mode Instruction and Command Instruction registers that store the control formats for device functional definition are located in the Read/Write Control Logic.
21	RESET	Reset	A "one" on this input forces the USART into the "Idle" mode where it will remain until reinitialized with a new set of control words. Minimum RESET pulse width is t_{CY}.
20	CLK	Clock Pulse	The CLK input provides for internal device timing and is usually connected to the Phase 2 (TTL) output of the μPB8224 Clock Generator. External inputs and outputs are not referenced to CLK, but the CLK frequency must be 30 times the Receiver or Transmitter clocks in the synchronous mode and 4.5 times for the asynchronous mode.
10	$\overline{WR}$	Write Data	A "zero" on this input instructs the μPD8251 and μPD8251A to accept the data or control word which the processor is writing out to the USART via the data bus.
13	$\overline{RD}$	Read Data	A "zero" on this input instructs the μPD8251 and μPD8251A to place the data or status information onto the Data Bus for the processor to read.
12	C/$\overline{D}$	Control/Data	The Control/Data input, in conjunction with the $\overline{WR}$ and $\overline{RD}$ inputs, informs USART to accept or provide either a data character, control word or status information via the Data Bus. 0 = Data; 1 = Control.
11	$\overline{CS}$	Chip Select	A "zero" on this input enables the USART for reading and writing to the processor.
Modem Control			The μPD8251 and μPD8251A have a set of control inputs and outputs which may be used to simplify the interface to a Modem.
22	$\overline{DSR}$	Data Set Ready	The Data Set Ready input can be tested by the processor via Status information. The $\overline{DSR}$ input is normally used to test Modem Data Set Ready condition.
24	$\overline{DTR}$	Data Terminal Ready	The Data Terminal Ready output can be controlled via the Command word. The $\overline{DTR}$ output is normally used to drive Modem Data Terminal Ready or Rate Select lines.
23	$\overline{RTS}$	Request to Send	The Request to Send output can be controlled via the Command word. The $\overline{RTS}$ output is normally used to drive the Modem Request to Send line.
17	$\overline{CTS}$	Clear to Send	A "zero" on the Clear to Send input enables the USART to transmit serial data if the TxEN bit in the Command Instruction register is enabled (one).

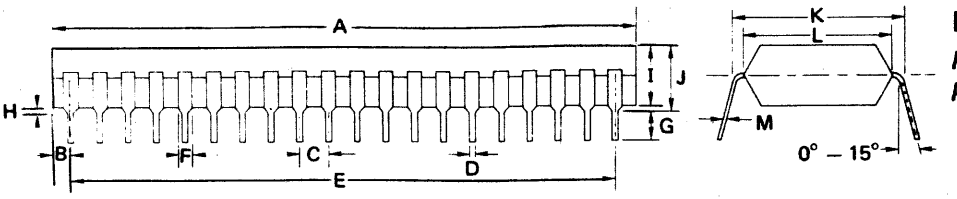
Notes: ① Instruction Code Designations r and p form the binary representation of the Registers and Ports involved.

② The dot under the appropriate flag bit indicates that its content is subject to change by the instruction it appears in.

③ References to the address and data are specified in bytes 2 and/or 1 of the instruction.



④ Numerical Subscripts appearing in the FUNCTION column reference the specific bits affected.

Symbol Definitions:

SYMBOL	DESCRIPTION
A	The Accumulator
AC	The Auxiliary Carry Flag
addr	Program Memory Address (12 bits)
Bb	Bit Designator (b = 0 – 7)
BS	The Bank Switch
BUS	The BUS Port
C	Carry Flag
CLK	Clock Signal
CNT	Event Counter
D	Nibble Designator (4 bits)
data	Number or Expression (8 bits)
DBF	Memory Bank Flip-Flop
F_0, F_1	Flags 0, 1
I	Interrupt
P	"In-Page" Operation Designator

SYMBOL	DESCRIPTION
P_p	Port Designator (p = 1, 2 or 4 – 7)
PSW	Program Status Word
Rr	Register Designator (r = 0, 1 or 0 – 7)
SP	Stack Pointer
T	Timer
TF	Timer Flag
T_0, T_1	Testable Flags 0, 1
X	External RAM
#	Prefix for Immediate Data
@	Prefix for Indirect Address
$	Program Counter's Current Value
(x)	Contents of External RAM Location
((x))	Contents of Memory Location Addressed by the Contents of External RAM Location.

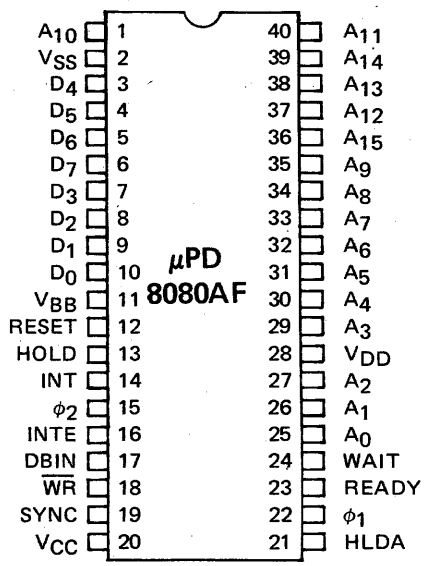
μPD8080AF 8-BIT N-CHANNEL MIROPROCESSOR FAMILY



DESCRIPTION

The μPD8080AF is a complete 8-bit parallel processor for use in general purpose digital computer systems. It is fabricated on a single LSI chip using N-channel silicon gate MOS process, which offers much higher performance than conventional microprocessors (1.28 μs minimum instruction cycle). A complete microcomputer system is formed when the μPD8080AF is interfaced with I/O ports (up to 256 input and 256 output ports) and any type or speed of semiconductor memory. It is available in a 40 pin ceramic or plastic package.

FEATURES

- 78 Powerful Instructions
- Three Devices — Three Clock Frequencies
  μPD8080AF — 2.0 MHz
  μPD8080AF-2 — 2.5 MHz
  μPD8080AF-1 — 3.0 MHz
- Direct Access to 64K Bytes of Memory with 16-Bit Program Counter
- 256 8-Bit Input Ports and 256 8-Bit Output Ports
- Double Length Operations Including Addition
- Automatic Stack Memory Operation with 16-Bit Stack Pointer
- TTL Compatible (Except Clocks)
- Multi-byte Interrupt Capability
- **Fully** Compatible with Industry Standard 8080A
- Available in either Plastic or Ceramic Package

PIN CONFIGURATION

Rev/1

©IC MASTER 1979

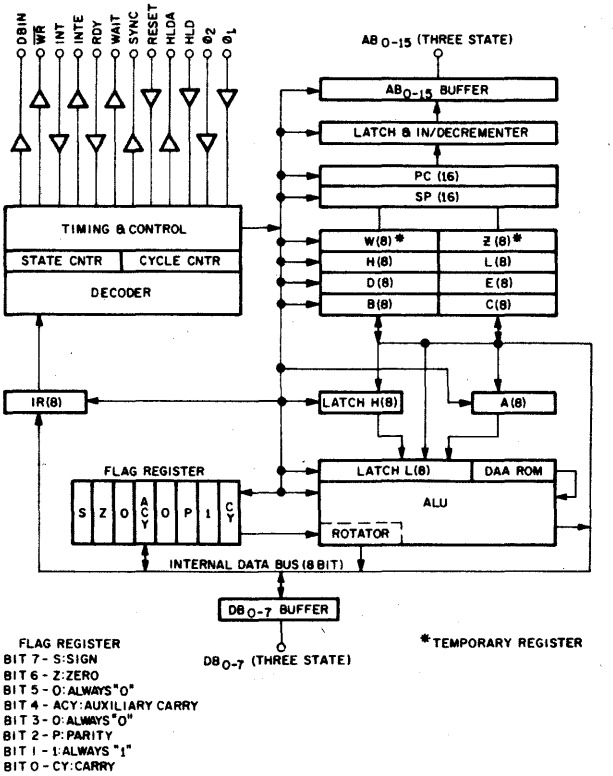
FUNCTIONAL DESCRIPTION

The μPD8080AF contains six 8-bit data registers, an 8-bit accumulator, four testable flag bits, and an 8-bit parallel binary arithmetic unit. The μPD8080AF also provides decimal arithmetic capability and it includes 16-bit arithmetic and immediate operators which greatly simplify memory address calculations, and high speed arithmetic operations.

The μPD8080AF utilizes a 16-bit address bus to directly address 64K bytes of memory, is fully TTL compatible (1.9 mA), and utilizes the following addressing modes: Direct; Register; Register Indirect; and Immediate.

The μPD8080AF has a stack architecture wherein any portion of the external memory can be used as a last in/first out (LIFO) stack to store/retrieve the contents of the accumulator, the flags, or any of the data registers.

The μPD8080AF also contains a 16-bit stack pointer to control the addressing of this external stack. One of the major advantages of the stack is that multiple level interrupts can easily be handled since complete system status can be saved when an interrupt occurs and then restored after the interrupt is complete. Another major advantage is that almost unlimited subroutine nesting is possible.



This processor is designed to greatly simplify system design. Separate 16-line address and 8-line bidirectional data busses are employed to allow direct interface to memories and I/O ports. Control signals, requiring no decoding, are provided directly by the processor. All busses, including the control bus, are TTL compatible.

Communication on both the address lines and the data lines can be interlocked by using the HOLD input. When the Hold Acknowledge (HLDA) signal is issued by the processor, its operation is suspended and the address and data lines are forced to be in the FLOATING state. This permits other devices, such as direct memory access channels (DMA), to be connected to the address and data busses.

The μPD8080AF has the capability to accept a multiple byte instruction upon an interrupt. This means that a CALL instruction can be inserted so that any address in the memory can be the starting location for an interrupt program. This allows the assignment of a separate location for each interrupt operation, and as a result no polling is required to determine which operation is to be performed.

NEC offers three versions of the μPD8080AF. These processors have all the features of the μPD8080AF except the clock frequency ranges from 2.0 MHz to 3.0 MHz. These units meet the performance requirements of a variety of systems while maintaining software and hardware compatibility with other 8080A devices.

BLOCK DIAGRAM

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
1, 25-27, 29-40	$A_{15} - A_0$	Address Bus (output three-state)	The address bus is used to address memory (up to 64K 8-bit words) or specify the I/O device number (up to 256 input and 256 output devices). A_0 is the least significant bit.
2	V_{SS}	Ground (input)	Ground
3-10	$D_7 - D_0$	Data Bus (input/ output three-state)	The bidirectional data bus communicates between the processor, memory, and I/O devices for instructions and data transfers. During each sync time, the data bus contains a status word that describes the current machine cycle. D_0 is the least significant bit.
11	V_{BB}	V_{BB} Supply Voltage (input)	-5V ± 5%
12	RESET	Reset (input)	If the RESET signal is activated, the program counter is cleared. After RESET, the program starts at location 0 in memory. The INTE and HLDA flip-flops are also reset. The flags, accumulator, stack pointer, and registers are not cleared. (Note: External synchronization is not required for the RESET input signal which must be active for a minimum of 3 clock periods.)
13	HOLD	Hold (input)	HOLD requests the processor to enter the HOLD state. The HOLD state allows an external device to gain control of the μPD8080AF address and data buses as soon as the μPD8080AF has completed its use of these buses for the current machine cycle. It is recognized under the following conditions: • The processor is in the HALT state. • The processor is in the T_2 or T_W stage and the READY signal is active. As a result of entering the HOLD state, the ADDRESS BUS ($A_{15} - A_0$) and DATA BUS ($D_7 - D_0$) are in their high impedance state. The processor indicates its state on the HOLD ACKNOWLEDGE (HLDA) pin.
14	INT	Interrupt Request (input)	The μPD8080AF recognizes an interrupt request on this line at the end of the current instruction or while halted. If the μPD8080AF is in the HOLD state, or if the Interrupt Enable flip-flop is reset, it will not honor the request.
15	ϕ_2	Phase Two (input)	Phase two of processor clock.
16	INTE ①	Interrupt Enable (output)	INTE indicates the content of the internal interrupt enable flip-flop. This flip-flop is set by the Enable (EI) or reset by the Disable (DI) interrupt instructions and inhibits interrupts from being accepted by the processor when it is reset. INTE is automatically reset (disabling further interrupts) during T_1 of the instruction fetch cycle (M_1) when an interrupt is accepted and is also reset by the RESET signal.
17	DBIN	Data Bus In (output)	DBIN indicates that the data bus is in the input mode. This signal is used to enable the gating of data onto the μPD8080AF data bus from memory or input ports.
18	$\overline{WR}$	Write (output)	$\overline{WR}$ is used for memory WRITE or I/O output control. The data on the data bus is valid while the $\overline{WR}$ signal is active ($\overline{WR}$ = 0).
19	SYNC	Synchronizing Signal (output)	The SYNC signal indicates the beginning of each machine cycle.
20	V_{CC}	V_{CC} Supply Voltage (input)	+5V ± 5%
21	HLDA	Hold Acknowledge (output)	HLDA is in response to the HOLD signal and indicates that the data and address bus will go to the high impedance state. The HLDA signal begins at: • T_3 for READ memory or input operations. • The clock period following T_3 for WRITE memory or OUTPUT operations. In either case, the HLDA appears after the rising edge of ϕ_1 and high impedance occurs after the rising edge of ϕ_2.
22	ϕ_1	Phase One (input)	Phase one of processor clock.
23	READY	Ready (input)	The READY signal indicates to the μPD8080AF that valid memory or input data is available on the μPD8080AF data bus. READY is used to synchronize the processor with slower memory or I/O devices. If after sending an address out, the μPD8080AF does not receive a high on the READY pin, the μPD8080AF enters a WAIT state for as long as the READY pin is low. (READY can also be used to single step the processor.)
24	WAIT	Wait (output)	The WAIT signal indicates that the processor is in a WAIT state.
28	V_{DD}	V_{DD} Supply Voltage (input)	+12V ± 5%

Note: ① After the EI instruction, the μPD8080AF accepts interrupts on the second instruction following the EI. This allows proper execution of the RET instruction if an interrupt operation is pending after the service routine.

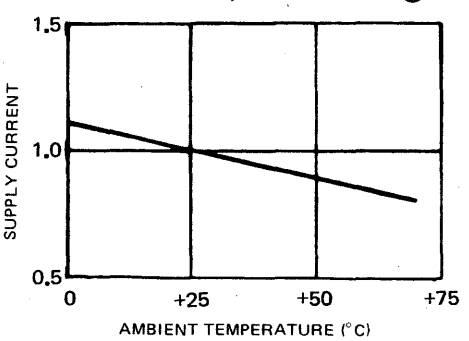
μPD8080AF

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature . . . . . 0°C to +70°C
Storage Temperature (Ceramic Package) . . . . . -65°C to +150°C
Storage Temperature (Plastic Package) . . . . . -40°C to +125°C
All Output Voltages ① . . . . . -0.3 to +20 Volts
All Input Voltages ① . . . . . -0.3 to +20 Volts
Supply Voltages V_{CC}, V_{DD} and V_{SS} ① . . . . . -0.3 to +20 Volts
Power Dissipation 1.5W
Note: ① Relative to V_{BB}.

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.



*T_a = 25°C

DC CHARACTERISTICS

T_a = 0°C to +70°C, V_{DD} = +12V ± 5%, V_{CC} = +5V ± 5%, V_{BB} = −5V ± 5%, V_{SS} = 0V, unless otherwise specified.

PARAMETER	SYMBOL	LIMITS MIN	TYP	MAX	UNIT	TEST CONDITIONS

Notes Continued:

④ The following are relevant when interfacing the μPD8080AF to devices having V_{IH} = 3.3V.

a. Maximum output rise time from 0.8V to 3.3V = 100 ns at C_L = SPEC.

b. Output delay when measured to 3.0V = SPEC +60 ns at C_L = SPEC.

c. If $C_L \neq$ SPEC, add 0.6 ns/pF if $C_L > C_{SPEC}$, subtract 0.3 ns/pF (from modified delay) if $C_L < C_{SPEC}$.

Address Hold Time after DBIN during HLDA	t_{AH} ②	−20			nsec	

Notes Continued: ⑤

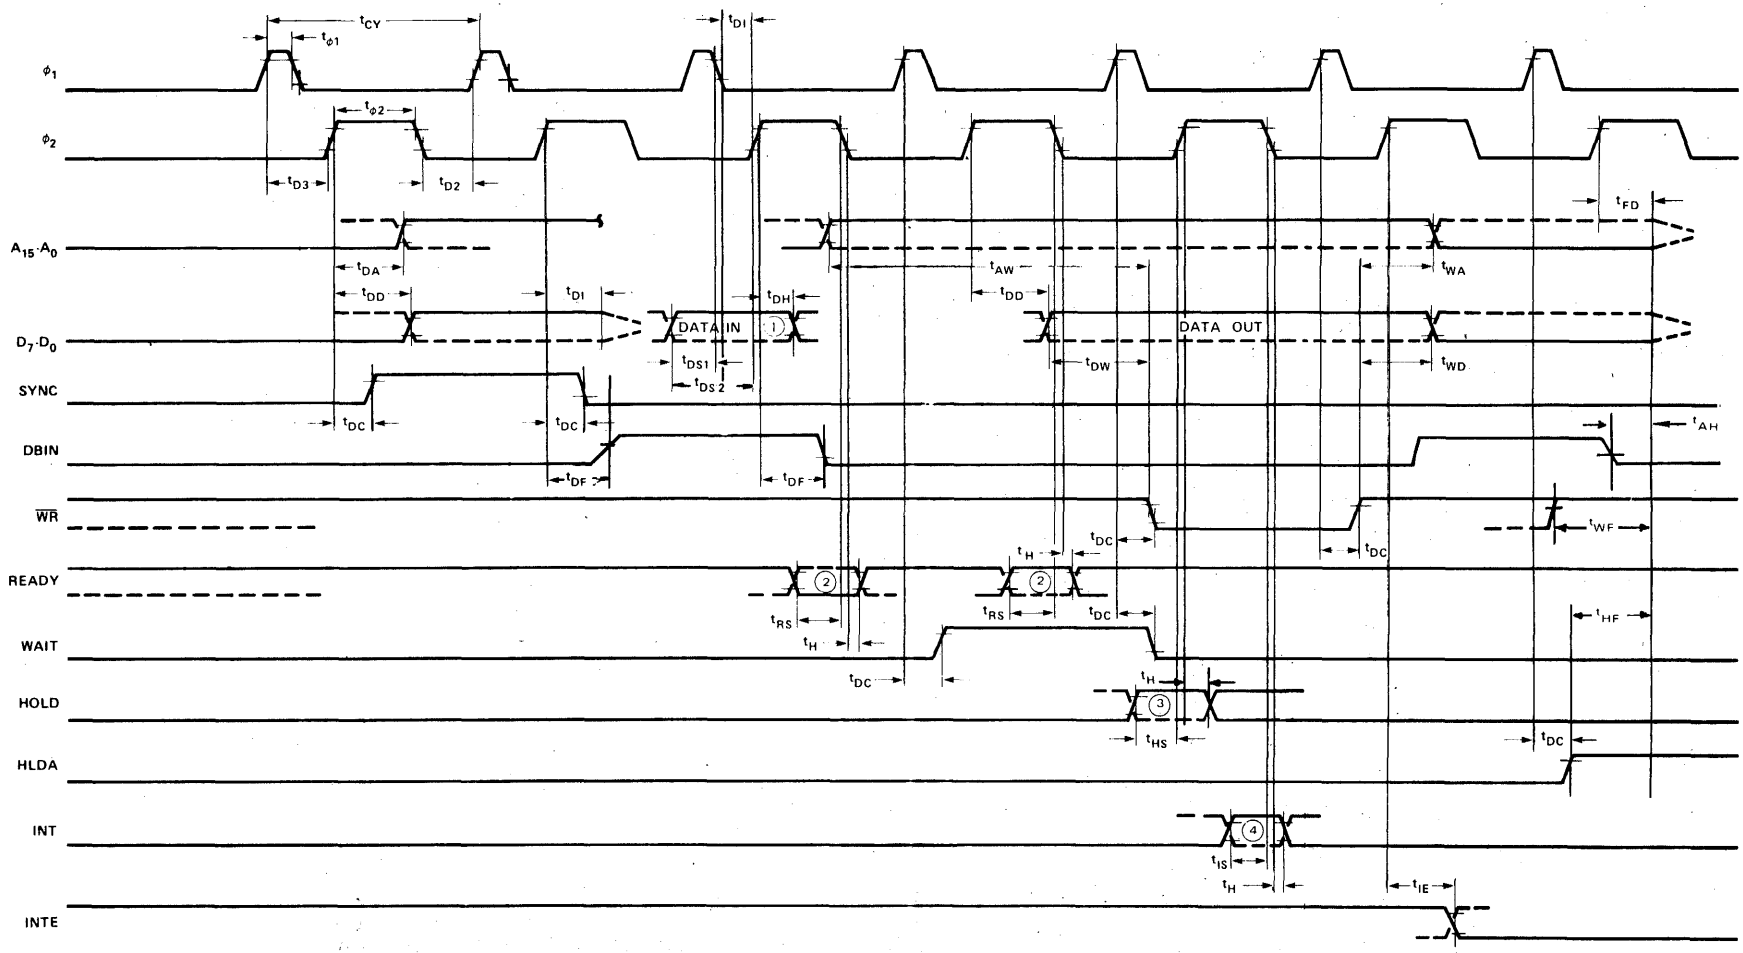
Device	t_{AW}
μPD8080AF	$2\,t_{CY} - t_{D3} - t_{r\phi2} - 140$
μPD8080AF-2	$2\,t_{CY} - t_{D3} - t_{r\phi2} - 130$
μPD8080AF-1	$2\,t_{CY} - t_{D3} - t_{r\phi2} - 110$

⑥

Device	t_{DW}
μPD8080AF	$t_{CY} - t_{D3} - t_{r\phi2} - 170$
μPD8080AF-2	$t_{CY} - t_{D3} - t_{r\phi2} - 170$
μPD8080AF-1	$t_{CY} - t_{D3} - t_{r\phi2} - 150$

⑦ If not HLDA, $t_{WD} = t_{WA} = t_{D3} + t_{r\phi2} + 10$ ns. If HLDA, $t_{WD} = t_{WA} = t_{WF}$.

⑧ $t_{HF} = t_{D3} + t_{r\phi2} - 50$ ns.



⑨ $t_{WF} = t_{D3} + t_{r\phi2} - 10$ ns.

TIMING WAVEFORMS (5)

(Note: Timing measurements are made at the following reference voltages: CLOCK "1" = 8.0V, "0" = 1.0V; INPUTS "1" = 3.3V, "0" = 0.8V; OUTPUTS "1" = 2.0V, "0" = 0.8V.)

Notes:
(1) Data in must be stable for this period during DBIN • T_3. Both t_{DS1} and t_{DS2} must be satisfied.
(2) Ready signal must be stable for this period during T_2 or T_W. (Must be externally synchronized.)
(3) Hold signal must be stable for this period during T_2 or T_W when entering hold mode, and during T_3, T_4, T_5 and T_{WH} when in hold mode. (External synchronization is not required.)
(4) Interrupt signal must be stable during this period of the last clock cycle of any instruction in order to be recognized in the following instruction. (External synchronization is not required.)
(5) This timing diagram shows timing relationships only; it does not represent any specific machine cycle.
(6) Timing measurements are made at the following reference voltages: CLOCK "1" = 8.0V, "0" = 1.0V; INPUTS "1" = 3.3V; "0" = 0.8V; OUTPUTS "1" = 2.0V, "0" = 0.8V.

INSTRUCTION SET

The instruction set includes arithmetic and logical operators with direct, register, indirect, and immediate addressing modes.

Move, load, and store instruction groups provide the ability to move either 8 or 16 bits of data between memory, the six working registers and the accumulator using direct, register, indirect, and immediate addressing modes.

The ability to branch to different portions of the program is provided with direct, conditional, or computed jumps. Also the ability to call and return from subroutines is provided both conditionally and unconditionally. The RESTART (or single byte call instruction) is useful for interrupt vector operation.

Conditional jumps, calls and returns execute based on the state of the four testable flags (Sign, Zero, Parity and Carry). The state of each flag is determined by the result of the last instruction executed that affected flags. (See Instruction Set Table.)

The Sign flag is set (High) if bit 7 of the result is a "1"; otherwise it is reset (Low). The Zero flag is set if the result is "0"; otherwise it is reset. The Parity flag is set if the modulo 2 sum of the bits of the result is "0" (Even Parity); otherwise (Odd Parity) it is reset. The Carry flag is set if the last instruction resulted in a carry or a borrow out of the most significant bit (bit 7) of the result; otherwise it is reset.

In addition to the four testable flags, the μPD8080AF has another flag (ACY) that is not directly testable. It is used for multiple precision arithmetic operations with the DAA instruction. The Auxiliary Carry flag is set if the last instruction resulted in a carry or a borrow from bit 3 into bit 4; otherwise it is reset.

Double precision operators such as stack manipulation and double add instructions extend both the arithmetic and interrupt handling capability of the μPD8080AF. The ability to increment and decrement memory, the six general registers and the accumulator are provided as well as extended increment and decrement instructions to operate on the register pairs and stack pointer. Further capability is provided by the ability to rotate the accumulator left or right through or around the carry bit.

Input and output may be accomplished using memory addresses as I/O ports or the directly addressed I/O provided for in the μPD8080AF instruction set.

The special instruction group completes the μPD8080AF instruction set: NOP, HALT stop processor execution; DAA provides decimal arithmetic capability; STC sets the carry flag; CMC complements it; CMA complements the contents of the accumulator; and XCHG exchanges the contents of two 16-bit register pairs directly.

DATA AND INSTRUCTION FORMATS

Data in the μPD8080AF is stored as 8-bit binary integers. All data/instruction transfers to the system data bus are in the following format:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0

MSB DATA WORD LSB

Instructions are one, two, or three bytes long. Multiple byte instructions must be stored in successive locations of program memory. The address of the first byte is used as the address of the instruction.

									TYPICAL INSTRUCTIONS
One Byte Instructions									
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	OP CODE	Register to register, memory reference, arithmetic or logical, rotate, return, push, pop, enable, or disable interrupt instructions
Two Byte Instructions									
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	OP CODE	Immediate mode or I/O instructions
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	OPERAND	
Three Byte Instructions									
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	OP CODE	Jump, call or direct load and store instructions
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	LOW ADDRESS OR OPERAND 1	
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	HIGH ADDRESS OR OPERAND 2

Notes:

[1]Operand Symbols used
A = 8-bit address or expression
s = source register
d = destination register
PSW = Processor Status Word
SP = Stack Pointer
D8 = 8-bit data quantity, expression, or constant, always B_2 of instruction
D16 = 16-bit data quantity, expression, or constant, always B_3B_2 of instruction
ADDR = 16-bit Memory address expression

[2]ddd or sss – 000 B – 001 C – 010 D – 011 E – 100 H – 101 L – 110 Memory – 111 A.

[3]Two possible cycle times (5/11) indicate instruction cycles dependent on condition flags.

[4]• = flag affected
= flag not affected
0 = flag reset
1 = flag set

©IC MASTER 1979

INSTRUCTION CYCLE TIMES

One to five machine cycles ($M_1 - M_5$) are required to execute an instruction. Each machine cycle involves the transfer of an instruction or data byte into the processor or a transfer of a data byte out of the processor (the sole exception being the double add instruction). The first one, two or three machine cycles obtain the instruction from the memory or an interrupting I/O controller. The remaining cycles are used to execute the instruction. Each machine cycle requires from three to five clock times ($T_1 - T_5$). During $\phi_1 \cdot$ SYNC of each machine cycle, a status word that identifies the type of machine cycle is available on the data bus.

Execution times and machine cycles used for each type of instruction are shown below.

INSTRUCTION	MACHINE CYCLES EXECUTED	CLOCK TIMES (MIN/MAX)
RST X and PUSH RP	PCR5 ① SPW3 ⑤ SPW3 ⑤	11

Machine Cycle Symbol Definition

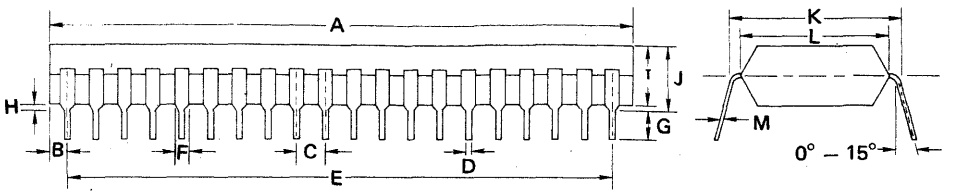
XX Y Z (N)
- XXYZ: Status word defining type of machine cycle (See Status Word Chart)
- Y: Number of clocks for this machine cycle
- Z: R = Read cycle – data into processor; W = Write cycle – data out of processor; X = No data transfer; PC = Program Counter used as address
- (N): Underlined (XXYZ(N)) indicates machine cycle is executed if condition is True.

XX:
- HL = Registers H and L used as address
- BC = Registers B and C used as address
- DE = Registers D and E used as address
- SP = Stack Pointer used as address
- BB = Byte 2 and 3 used as address
- AB = Byte 2 used as address

©IC MASTER 1979

STATUS INFORMATION DEFINITION

SYMBOLS	DATA BUS BIT	DEFINITION
INTA ①	D_0	Acknowledge signal for INTERRUPT request. Signal should be used to gate a restart or CALL instruction onto the data bus when DBIN is active.
$\overline{WO}$	D_1	Indicates that the operation in the current machine cycle will be a WRITE memory or OUTPUT function ($\overline{WO}$ = 0). Otherwise, a READ memory or INPUT operation will be executed.
STACK	D_2	Indicates that the address bus holds the pushdown stack address from the Stack Pointer.
HLTA	D_3	Acknowledge signal for HALT instruction.
OUT	D_4	Indicates that the address bus contains the address of an output device and the data bus will contain the output data when $\overline{WR}$ is active.
M_1	D_5	Provides a signal to indicate that the CPU is in the fetch cycle for the first byte of an instruction.
INP ①	D_6	Indicates that the address bus contains the address of an input device and the input data should be placed on the data bus when DBIN is active.
MEMR ①	D_7	Designates that the data bus will be used for memory read data.



Note: ① These three status bits can be used to control the flow of data onto the μPD8080AF data bus.

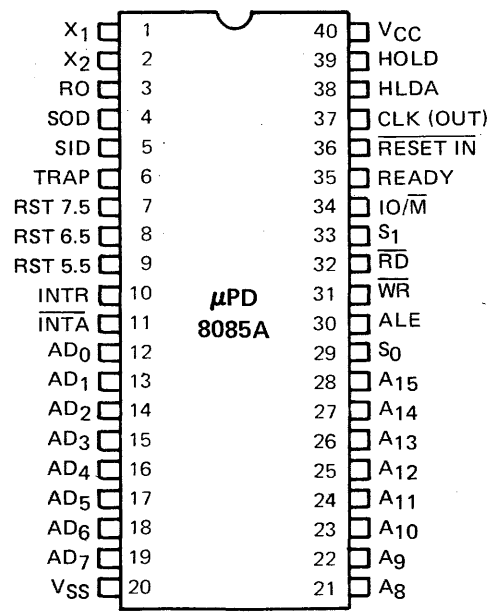
μPD8085A SINGLE CHIP 8-BIT N-CHANNEL MICROPROCESSOR



DESCRIPTION

The μPD8085A is a single chip 8-bit microprocessor which is 100 percent software compatible with the industry standard 8080A. It has the ability of increasing system performance of the standard 8080A by operating at a higher speed. Using the μPD8085A in conjunction with its family of ICs allows the designer complete flexibility with minimum chip count.

FEATURES

- Single Power Supply: +5 Volt
- Internal Clock Generation and System Control
- Internal Serial In/Out Port.
- Fully TTL Compatible
- Internal 4-Level Interrupt Structure
- Multiplexed Address/Data Bus for Increased System Performance
- Complete Family of Components for Design Flexibility
- Software Compatible with Standard 8080A
- Available in Either Plastic or Ceramic Package

PIN CONFIGURATION

©IC MASTER 1979

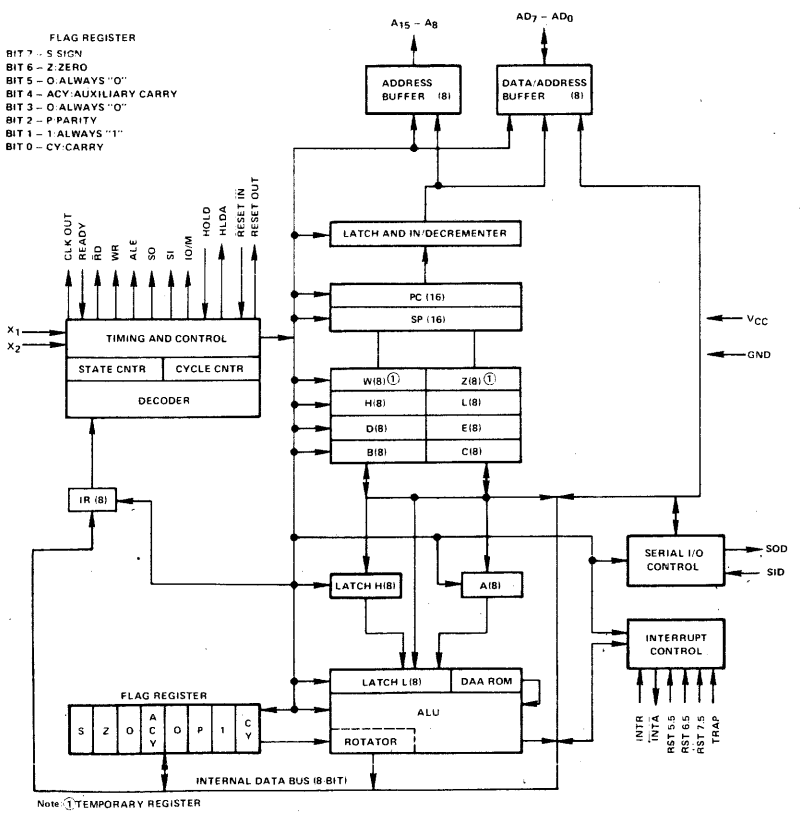
FUNCTIONAL DESCRIPTION

The μPD8085A contains six 8-bit data registers, an 8-bit accumulator, four testable flag bits, and an 8-bit parallel binary arithmetic unit. The μPD8085A also provides decimal arithmetic capability and it includes 16-bit arithmetic and immediate operators which greatly simplify memory address calculations, and high speed arithmetic operations.

The μPD8085A has a stack architecture wherein any portion of the external memory can be used as a last in/first out (LIFO) stack to store/retrieve the contents of the accumulator, the flags, or any of the data registers.

The μPD8085A also contains a 16-bit stack pointer to control the addressing of this external stack. One of the major advantages of the stack is that multiple level interrupts can easily be handled since complete system status can be saved when an interrupt occurs and then restored after the interrupt is complete. Another major advantage is that almost unlimited subroutine nesting is possible.

The μPD8085A was designed with speed and simplicity of the overall system in mind. The multiplexed address/data bus increases available pins for advanced functions in the processor and peripheral chips while providing increased system speed and less critical timing functions. All signals to and from the μPD8085A are fully TTL compatible.



The internal interrupt structure of the μPD8085A features 4 levels of prioritized interrupt with three levels internally maskable.

Communication on both the address lines and the data lines can be interlocked by using the HOLD input. When the Hold Acknowledge (HLDA) signal is issued by the processor, its operation is suspended and the address, data and control lines are forced to be in the FLOATING state. This permits other devices, such as direct memory access channels (DMA), to be connected to the address and data busses.

The μPD8085A features internal clock generation with status outputs available for advanced read/write timing and memory/IO instruction indications. The clock may be crystal controlled, RC controlled, or driven by an external signal.

On chip serial in/out port is available and controlled by the newly added RIM and SIM instructions.

BLOCK DIAGRAM

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
1, 2	X_1, X_2	Crystal In	Crystal, RC, or external clock input
3	RO	Reset Out	Acknowledge that the processor is being reset to be used as a system reset
4	SOD	Serial Out Data	1-bit data out by the SIM instruction
5	SID	Serial In Data	1-bit data into ACC bit 7 by the RIM instruction
6	Trap	Trap Interrupt Input	Highest priority nonmaskable restart interrupt
7 8 9	RST 7.5 RST 6.5 RST 5.5	Restart Interrupts	Priority restart interrupt inputs, of which 7.5 is the highest and 5.5 the lowest priority
10	INTR	Interrupt Request In	A general interrupt input which stops the PC from incrementing, generates $\overline{INTA}$, and samples the data bus for a restart or call instruction
11	$\overline{INTA}$	Interrupt Acknowledge	An output which indicates that the processor has responded to INTR
12-19	$AD_0 - AD_7$	Low Address/Data Bus	Multiplexed low address and data bus
20	V_{SS}	Ground	Ground Reference
21-28	$A_8 - A_{15}$	High Address Bus	Nonmultiplexed high 8-bits of the address bus
29, 33	S_0, S_1	Status Outputs	Outputs which indicate data bus status: Halt, Write, Read, Fetch
30	ALE	Address Latch Enable Out	A signal which indicates that the lower 8-bits of address are valid on the AD lines
31, 32	$\overline{WR}$, $\overline{RD}$	Write/Read Strobes Out	Signals out which are used as write and read strobes for memory and I/O devices
34	IO/$\overline{M}$	I/O or Memory Indicator	A signal out which indicates whether $\overline{RD}$ or $\overline{WR}$ strobes are for I/O or memory devices
35	Ready	Ready Input	An input which is used to increase the data and address bus access times (can be used for slow memory)
36	$\overline{Reset\ In}$	Reset Input	An input which is used to start the processor activity at address 0, resetting IE and HLDA flip-flops
37	CLK	Clock Out	System Clock Output
38, 39	HLDA, HOLD	Hold Acknowledge Out and Hold Input Request	Used to request and indicate that the processor should relinquish the bus for DMA activity. When hold is acknowledged, $\overline{RD}$, $\overline{WR}$, IO/$\overline{M}$, Address and Data busses are all 3-stated.
40	V_{CC}	5V Supply	Power Supply Input

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	0°C to +70°C
Storage Temperature (Ceramic Package)	−65°C to +150°C
(Plastic Package)	−40°C to +125°C
All Output Voltages	−0.3 to +7 Volts
All Input Voltages	−0.3 to +7 Volts
Supply Voltage V_{CC}	−0.3 to +7 Volts
Power Dissipation	1.5W

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

*T_a = 25°C

DC CHARACTERISTICS

T_a = 0°C to +70°C, V_{CC} = +5V ± 5%, V_{SS} = GND, unless otherwise specified

PARAMETER	SYMBOL	LIMITS MIN	LIMITS TYP	LIMITS MAX	UNIT	TEST CONDITIONS
Input Low Voltage	V_{IL}	V_{SS} − 0.5		V_{SS} + 0.8	V	
Input High Voltage	V_{IH}	2.0		V_{CC} + 0.5	V	
Output Low Voltage	V_{OL}			0.45	V	I_{OL} = 2 mA on all outputs
Output High Voltage	V_{OH}	2.4			V	I_{OH} = −400 μs ①
Power Supply Current (V_{CC})	I_{CC} (AV)			170	mA	t_{CY} min
Input Leakage	I_{IL}			±10 ①	μA	$V_{IN} = V_{CC}$
Output Leakage	I_{LO}			±10 ①	μA	$0.45V \leq V_{OUT} \leq V_{CC}$
Input Low Level, Reset	V_{ILR}	−0.5		+0.8	V	
Input High Level, Reset	V_{IHR}	2.4		V_{CC} + 0.5	V	
Hysteresis, Reset	V_{HY}	0.25			V	

Note: ① Minus (−) designates current flow out of the device.

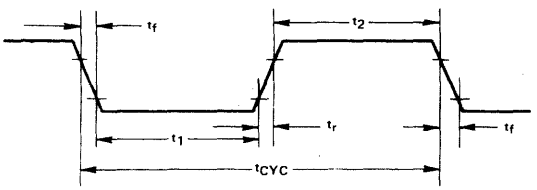
AC CHARACTERISTICS



T_a = 0°C to +70°C; V_{CC} = 5V ± 5%; V_{SS} = 0V

PARAMETER	SYMBOL	LIMITS MIN	TYP	MAX	UNIT	TEST CONDITIONS
CLK Cycle Period	T_{CYC}	320		2000	ns	
CLK Low Time	t_1	80			ns	
CLK High Time	t_2	120			ns	
CLK Rise and Fall Time	t_r, t_f			30	ns	T_{CYC} = 320 ns
Address Valid Before Trailing Edge of ALE	t_{AL}	110			ns	C_L = 150 pF
Address Hold Time After ALE	t_{LA}	100			ns	
ALE Width	t_{LL}	140			ns	
ALE Low During CLK High	t_{LCK}	100			ns	Output Voltages:
Trailing Edge of ALE to Leading Edge of Control	t_{LC}	130			ns	V_L = 0.8 Volts
Address Float After Leading Edge of $\overline{READ}$ ($\overline{INTA}$)	t_{AFR}			0	ns	V_H = 2.0 Volts
Valid Address to Valid Data In	t_{AD}			575	ns	Input Voltages:
$\overline{READ}$ (or $\overline{INTA}$) to Valid Data	t_{RD}			300	ns	V_L = 0.8 Volts
Data Hold Time After $\overline{READ}$ ($\overline{INTA}$)	t_{RDH}	0			ns	V_H = 1.5 Volts at 20 ns rise and fall times
Trailing Edge of $\overline{READ}$ to Re-Enabling of Address	t_{RAE}	150			ns	
Address (A_8-A_{15}) Valid After Control ①	t_{CA}	120			ns	For outputs where C_L ≠ 150 pf, correct as follows:
Data Valid to Trailing Edge of $\overline{WRITE}$	t_{DW}	420			ns	
Data Valid After Trailing Edge of $\overline{WRITE}$	t_{WD}	100			ns	25 pf ≤ CL < 150 pf -0.10 ns/pf
Width of Control Low ($\overline{RD}$, $\overline{WR}$, $\overline{INTA}$)	t_{CC}	400			ns	
Trailing Edge of Control to Leading Edge of ALE	t_{CL}	50			ns	
READY Valid from Address Valid	t_{ARY}			220	ns	150 pf < CL ≤ 300 pf + 0.30 ns/pf
READY Setup Time to Leading Edge of CLK	t_{RYS}	110			ns	
READY Hold Time	t_{RYH}	0			ns	
HLDA Valid to Trailing Edge of CLK	t_{HACK}	110			ns	Outputs measured with only capacitive load
Bus Float After HLDA	t_{HABF}			210	ns	
HLDA to Bus Enable	t_{HABE}			210	ns	
ALE to Valid Data In	t_{LDR}			460	ns	
Control Trailing Edge to Leading Edge of Next Control	t_{RV}	400			ns	
Address Valid to Leading Edge of Control	t_{AC}	270			ns	
HOLD Setup Time to Trailing Edge of CLK	t_{HDS}	170			ns	
HOLD Hold Time	t_{HDH}	0			ns	
INTR Setup Time to Leading Edge of CLK (M1, T1 only). Also RST and TRAP	t_{INS}	160			ns	
INTR Hold Time	t_{INH}	0			ns

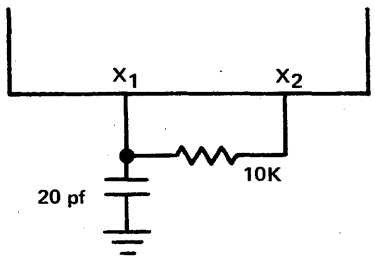
PROCESSOR STATE TRANSITION DIAGRAM

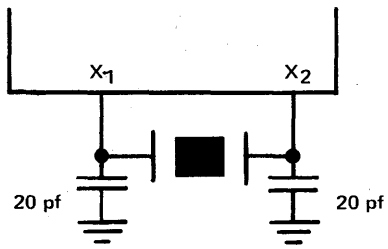
Notes: ① BI indicates that the bus is idle during this machine cycle.



② CK indicates the number of clock cycles in this machine cycle.

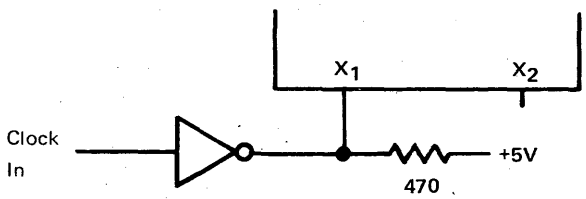
©IC MASTER 1979

CLOCK INPUTS ①



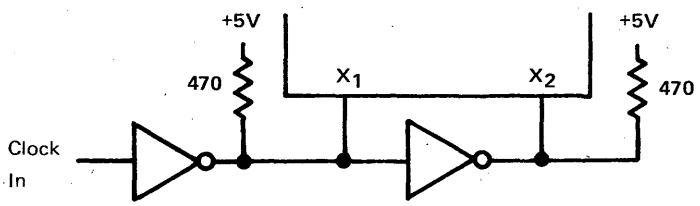
As stated, the timing for the μPD8085A may be generated in one of three ways; crystal, RC, or external clock. Recommendations for these methods are shown below.

RC



≈3 MHz Input Frequency
RC Resonance

CRYSTAL



1-6 MHz Input Frequency
Parallel Resonant Crystal

EXTERNAL

1-6 MHz 25-50% DC
X_2 not used

1-6 MHz > 50% DC

Note: ① Input frequency must be twice the internal operating frequency.

STATUS OUTPUTS

The Status Outputs are valid during ALE time and have the following meaning:

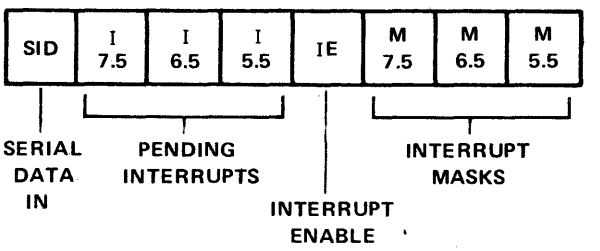
	S1	S0
Halt	0	0
Write	0	1
Read	1	0
Fetch	1	1

These pins may be decoded to portray the processor's data bus status.

©IC MASTER 1979

INTERRUPTS

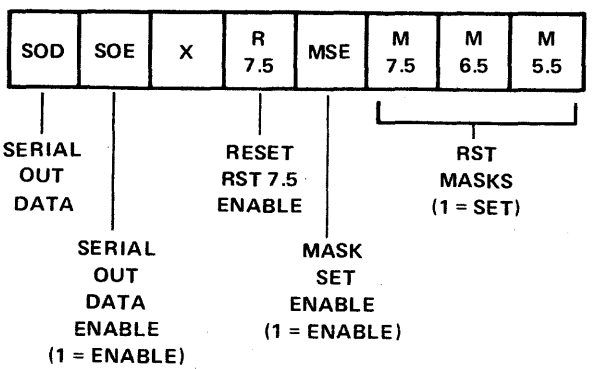
The μPD8085A has five interrupt pins available to the user. INTR is operationally the same as the 8080 interrupt request, three (3) internally maskable restart interrupts: RESTART 5.5, 6.5 and 7.5, and TRAP, a nonmaskable restart.



PRIORITY	INTERRUPT	RESTART ADDRESS
Highest	TRAP	24_{16}
|	RST 5.5	$2C_{16}$
|	RST 6.5	34_{16}
|	RST 7.5	$3C_{16}$
Lowest	INTR	

INTR, RST 5.5 and RST 6.5 are all level sensing inputs while RST 7.5 is set on a rising edge. TRAP, the highest priority interrupt, is nonmaskable and is set on the rising edge or positive level. It must make a low to high transition and remain high to be seen, but it will not be generated again until it makes another low to high transition.

SERIAL I/O



Serial input and output is accomplished with two new instructions not included in the 8080: RIM and SIM. These instructions serve several purposes: serial I/O, and reading or setting the interrupt mask.

The RIM (Read Interrupt Mask) instruction is used for reading the interrupt mask and for reading serial data. After execution of the RIM instruction the ACC content is as follows:

Note: After the TRAP interrupt, the RIM instruction must be executed to preserve the status of IE.

The SIM (Set Interrupt Mask) instruction is used to program the interrupt mask and to output serial data. Presetting the ACC for the SIM instruction has the following meaning:

©IC MASTER 1979

INSTRUCTION SET

The instruction set includes arithmetic and logical operators with direct, register, indirect, and immediate addressing modes.

Move, load, and store instruction groups provide the ability to move either 8 or 16 bits of data between memory, the six working registers and the accumulator using direct, register, indirect, and immediate addressing modes.

The ability to branch to different portions of the program is provided with direct, conditional, or computed jumps. Also, the ability to call and return from subroutines is provided both conditionally and unconditionally. The RESTART (or single byte call instruction) is useful for interrupt vector operation.

Conditional jumps, calls and returns execute based on the state of the four testable flags (Sign, Zero, Parity and Carry). The state of each flag is determined by the result of the last instruction executed that affected flags. (See Instruction Set Table.)

The Sign flag is set (High) if bit 7 of the result is a "1"; otherwise it is reset (Low). The Zero flag is set if the result is "0"; otherwise it is reset. The Parity flag is set if the modulo 2 sum of the bits of the result is "0" (Even Parity); otherwise (Odd Parity) it is reset. The Carry flag is set if the last instruction resulted in a carry or a borrow out of the most significant bit (bit 7) of the result; otherwise it is reset.

In addition to the four testable flags, the μPD8085A has another flag (ACY) that is not directly testable. It is used for multiple precision arithmetic operations with the DAA instruction. The Auxiliary Carry flag is set if the last instruction resulted in a carry or a borrow from bit 3 into bit 4; otherwise it is reset.

Double precision operators such as stack manipulation and double add instructions extend both the arithmetic and interrupt handling capability of the μPD8085A. The ability to increment and decrement memory, the six general registers and the accumulator are provided as well as extended increment and decrement instructions to operate on the register pairs and stack pointer. Further capability is provided by the ability to rotate the accumulator left or right through or around the carry bit.

Input and output may be accomplished using memory addresses as I/O ports or the directly addressed I/O provided for in the μPD8085A instruction set.

Two instructions, RIM and SIM, are used for reading and setting the internal interrupt mask as well as input and output to the serial I/O port.

The special instruction group completes the μPD8085A instruction set: NOP, HALT stop processor execution; DAA provides decimal arithmetic capability; STC sets the carry flag; CMC complements it; CMA complements the contents of the accumulator; and XCHG exchanges the contents of two 16-bit register pairs directly.

DATA AND INSTRUCTION FORMATS

Data in the μPD8085A is stored as 8-bit binary integers. All data/instruction transfers to the system data bus are in the following format:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0

MSB DATA WORD LSB

Instructions are one, two, or three bytes long. Multiple byte instructions must be stored in successive locations of program memory. The address of the first byte is used as the address of the instruction.

									TYPICAL INSTRUCTIONS
One Byte Instructions									
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	OP CODE	Register to register, memory reference, arithmetic or logical, rotate, return, push, pop, enable, or disable interrupt instructions
Two Byte Instructions									
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	OP CODE	Immediate mode or I/O instructions
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	OPERAND	
Three Byte Instructions									
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	OP CODE	Jump, call or direct load and store instructions
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	LOW ADDRESS OR OPERAND 1	
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	HIGH ADDRESS OR OPERAND 2

Notes:

[1] Operand Symbols used
- A = 8-bit address or expression
- s = source register
- d = destination register
- PSW = Processor Status Word
- SP = Stack Pointer
- D8 = 8-bit data quantity, expression, or constant, always B_2 of instruction
- D16 = 16-bit data quantity, expression, or constant, always B_3B_2 of instruction
- ADDR = 16-bit Memory address expression

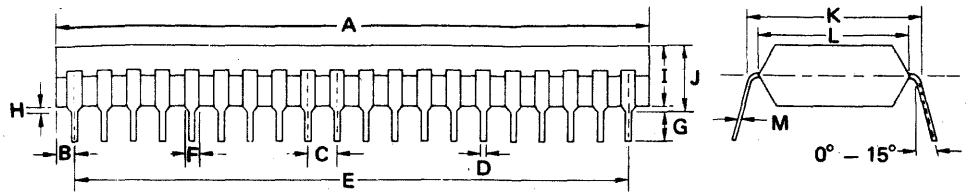
[2] ddd or sss – 000 B – 001 C – 010 D – 011 E – 100 H – 101 L – 110 Memory – 111 A.

[3] Two possible cycle times (7/10) indicate instruction cycles dependent on condition flags.

[4] • = flag affected
- flag not affected
0 = flag reset
1 = flag set

©IC MASTER 1979

INSTRUCTION CYCLE TIMES



One to five machine cycles ($M_1 - M_5$) are required to execute an instruction. Each machine cycle involves the transfer of an instruction or data byte into the processor or a transfer of a data byte out of the processor (the sole exception being the double add instruction). The first one, two or three machine cycles obtain the instruction from the memory or an interrupting I/O controller. The remaining cycles are used to execute the instruction. Each machine cycle requires from three to five clock times ($T_1 - T_5$).

Machine cycles and clock states used for each type of instruction are shown below.

μPD8085A FAMILY MINIMUM SYSTEM CONFIGURATION

A minimum computer system consisting of a processor, ROM, RAM, and I/O can be built with only 3-40 pin packs. This system is shown below with its address, data, control busses and I/O ports.

FEATURES OF μPD8085A MINIMUM SYSTEM
2K – BYTE ROM
256 – BYTE RAM
1 – INTERVAL TIMER
4 – 8-BIT I/O PORTS
1 – 6-BIT I/O-STATUS
4 – INTERRUPT LEVELS

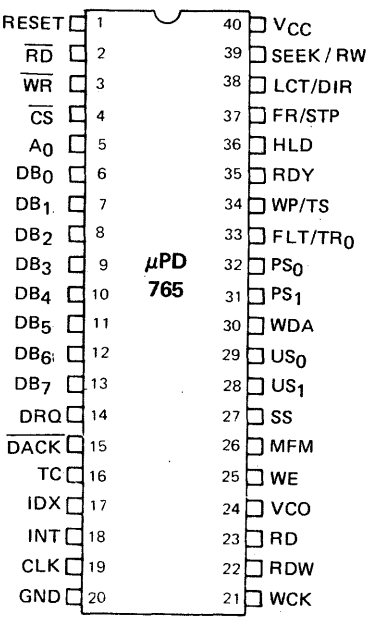
SINGLE/DOUBLE DENSITY FLOPPY DISK CONTROLLER

DESCRIPTION

The μPD765 is a LSI Floppy Disk Controller (FDC) Chip, which contains the circuitry and control functions for interfacing a processor to 4 Floppy Disk Drives. It is capable of supporting either IBM 3740 single density format (FM), or IBM System 34 Double Density format (MFM) including double sided recording. The μPD765 provides control signals which simplify the design of an external phase locked loop, and write precompensation circuitry. The FDC simplifies and handles most of the burdens associated with implementing a Floppy Disk Interface.

Hand-shaking signals are provided in the μPD765 which make DMA operation easy to incorporate with the aid of an external DMA Controller chip, such as the μPD8257. The FDC will operate in either DMA or Non-DMA mode. In the Non-DMA mode, the FDC generates interrupts to the processor every time a data byte is available. In the DMA mode, the processor need only load the command into the FDC and all data transfers occur under control of the μPD765 and DMA controller.

There are 15 separate commands which the μPD765 will execute. Each of these commands require multiple 8-bit bytes to fully specify the operation which the processor wishes the FDC to perform. The following commands are available:



Read Data	Scan High or Equal	Write Deleted Data
Read ID	Scan Low or Equal	Seek
Read Deleted Data	Specify	Recalibrate (Restore to Track 0)
Read a Track	Write Data	Sense Interrupt Status
Scan Equal	Format a Track	Sense Drive Status

FEATURES

Address mark detection circuitry is internal to the FDC which simplifies the phase locked loop and read electronics. The track stepping rate, head load time, and head unload time may be programmed by the user. The μPD765 offers many additional features such as multiple sector transfers in both read and write with a single command, and full IBM compatibility in both single and double density modes.

- IBM Compatible in Both Single and Double Density Recording Formats
- Programmable Data Record Lengths: 128, 256, 512, or 1024 Bytes/Sector
- Multi-Sector and Multi-Track Transfer Capability
- Drive Up to 4 Floppy Disks
- Data Scan Capability – Will Scan a Single Sector or an Entire Cylinder's Worth of Data Fields, Comparing on a Byte by Byte Basis, Data in the Processor's Memory with Data Read from the Diskette
- Data Transfers in DMA or Non-DMA Mode
- Parallel Seek Operations on Up to Four Drives
- Compatible with Most Microprocessors Including 8080A, 8085A, μPD780 (Z80™)
- Single Phase 8 MHz Clock
- Single +5 Volt Power Supply
- Available in 40 Pin Plastic Dual-in-Line Package

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	PIN NAME	INPUT/ OUTPUT	CONNECTION TO	FUNCTION
1	RST	Reset	Input	Processor	Places FDC in idle state. Resets output lines to FDD to "0" (low).
2	$\overline{RD}$	Read	Input①	Processor	Control signal for transfer of data from FDC to Data Bus, when "0" (low).
3	$\overline{WR}$	Write	Input①	Processor	Control signal for transfer of data to FDC via Data Bus, when "0" (low).
4	$\overline{CS}$	Chip Select	Input	Processor	IC selected when "0" (low), allowing $\overline{RD}$ and $\overline{WR}$ to be enabled.
5	A_0	Data/Status Reg Select	Input①	Processor	Selects Data Reg (A_0=1) or Status Reg (A_0=0) contents of the FDC to be sent to Data Bus.
6-13	DB_0-DB_7	Data Bus	Input/① Output	Processor	Bi-Directional 8-bit Data Bus.
14	DRQ	Data DMA Request	Output	DMA	DMA Request is being made by FDC when DRQ="1".
15	$\overline{DACK}$	DMA Acknowledge	Input	DMA	DMA cycle is active when "0" (low) and Controller is performing DMA transfer.
16	TC	Terminal Count	Input	DMA	Indicates the termination of a DMA transfer when "1" (high).
17	IDX	Index	Input	FDD	Indicates the beginning of a disk track.
18	INT	Interrupt	Output	Processor	Interrupt Request Generated by FDC.
19	CLK	Clock	Input		Single Phase 8 MHz Squarewave Clock.
20	GND	Ground			D.C. Power Return.
21	WCK	Write Clock	Input		Write data rate to FDD. FM = 500 kHz, MFM = 1 MHz, with a pulse width of 250 ns for both FM and MFM.
22	RDW	Read Data Window	Input	Phase Lock Loop	Generated by PLL, and used to sample data from FDD.
23	RDD	Read Data	Input	FDD	Read data from FDD, containing clock and data bits.
24	VCO	VCO Sync	Output	Phase Lock Loop	Inhibits VCO in PLL when "0" (low), enables VCO when "1".
25	WE	Write Enable	Output	FDD	Enables write data into FDD.
26	MFM	MFM Mode	Output	Phase Lock Loop	MFM mode when "1", FM mode when "0".
27	SS	Side Select	Output	FDD	Head 1 selected when "1" (high), Head 0 selected when "0" (low).
28, 29	US_1, US_0	Unit Select	Output	FDD	FDD Unit Selected.
30	WDA	Write Data	Output	FDD	Serial clock and data bits to FDD.
31, 32	PS_1, PS_0	Precompensation	Output	FDD	Write precompensation status during MFM mode. Determines early, late, and normal times.
33	FLT/TR_0	Fault/Track 0	Input	FDD	Senses FDD fault condition, in Read/ Write mode; and Track 0 condition in Seek mode.
34	WP/TS	Write Protect/ Two-Side	Input	FDD	Senses Write Protect status in Read/ Write mode; and Two Side Media in Seek mode.
35	RDY	Ready	Input	FDD	Indicates FDD is ready to send or receive data.
36	HLD	Head Load	Output	FDD	Command which causes read/write head in FDD to contact diskette.
37	FR/STP	Flt Reset/Step	Output	FDD	Resets fault F.F. in FDD in Read/Write mode, contains step pulses to move head to another cylinder in Seek mode.
38	LCT/DIR	Low Current/ Direction	Output	FDD	Lowers Write current on inner tracks in Read/Write mode, determines direction head will step in Seek mode.
39	SEEK/RW	SEEK/Read Write	Output	FDD	When "1" (high) Seek mode selected and when "0" (low) Read/Write mode selected.
40	V_{CC}	+5V			D.C. Power

Note: ① Disabled when $\overline{CS}$ = 1.

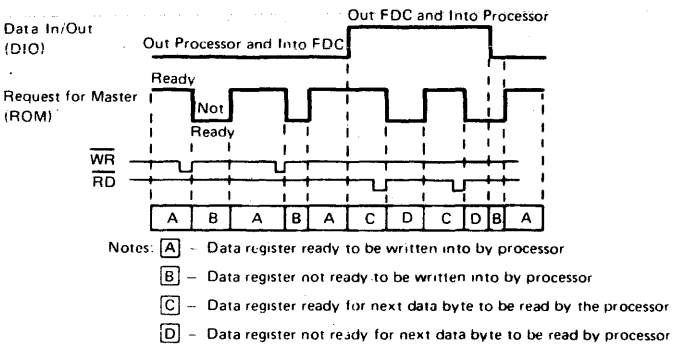
INTERNAL REGISTERS

The μPD765 contains two registers which may be accessed by the main system processor; a Status Register and a Data Register. The 8-bit Status Register contains the status information of the FDC, and may be accessed at any time. The 8-bit Data Register (actually consists of several registers in a stack with only one register presented to the data bus at a time), which stores data, commands, parameters, and FDD status information. Data bytes are read out of, or written into, the Data Register in order to program or obtain the results after a particular command. The Status Register may only be read and is used to facilitate the transfer of data between the processor and μPD765.

The relationship between the Status/Data registers and the signals $\overline{RD}$, $\overline{WR}$, and A_0 is shown below.

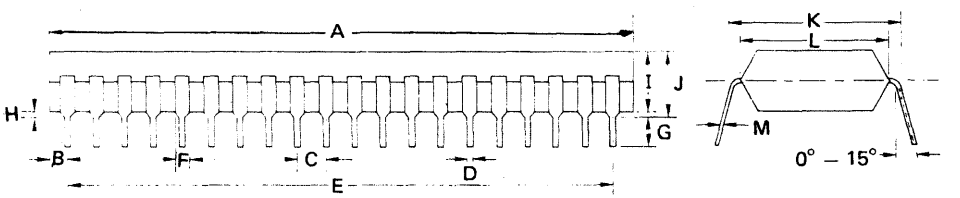
A_0	$\overline{RD}$	$\overline{WR}$	FUNCTION
0	0	1	Read Status Register
0	1	0	Illegal
0	0	0	Illegal
1	0	0	Illegal
1	0	1	Read from Data Register
1	1	0	Write into Data Register



©IC MASTER 1979

INTERNAL REGISTERS (CONT.)

The bits in the Status Register are defined as follows:



BIT NUMBER	NAME	SYMBOL	DESCRIPTION
DB_0	FDD 0 Busy	D_0B	FDD number 0 is in the Seek mode.
DB_1	FDD 1 Busy	D_1B	FDD number 1 is in the Seek mode.
DB_2	FDD 2 Busy	D_2B	FDD number 2 is in the Seek mode.
DB_3	FDD 3 Busy	D_3B	FDD number 3 is in the Seek mode.
DB_4	FDC Busy	CB	A read or write command is in process.
DB_5	Non-DMA mode	NDM	The FDC is in the non-DMA mode.
DB_6	Data Input/Output	DIO	Indicates direction of data transfer between FDC and Data Register. If DIO = "1" then transfer is from Data Register to the Processor. If DIO = "0", then transfer is from the Processor to Data Register.
DB_7	Request for Master	RQM	Indicates Data Register is ready to send or receive data to or from the Processor. Both bits DIO and RQM should be used to perform the handshaking functions of "ready" and "direction" to the processor.

The DIO and RQM bits in the Status Register indicate when Data is ready and in which direction data will be transferred on the Data Bus.

Notes: A – Data register ready to be written into by processor
B – Data register not ready to be written into by processor
C – Data register ready for next data byte to be read by the processor
D – Data register not ready for next data byte to be read by processor

COMMAND SEQUENCE

The μPD765 is capable of performing 15 different commands. Each command is initiated by a multi-byte transfer from the processor, and the result after execution of the command may also be a multi-byte transfer back to the processor. Because of this multi-byte interchange of information between the μPD765 and the processor, it is convenient to consider each command as consisting of three phases:

Command Phase: The FDC receives all information required to perform a particular operation from the processor.

Execution Phase: The FDC performs the operation it was instructed to do.

Result Phase: After completion of the operation, status and other housekeeping information are made available to the processor.

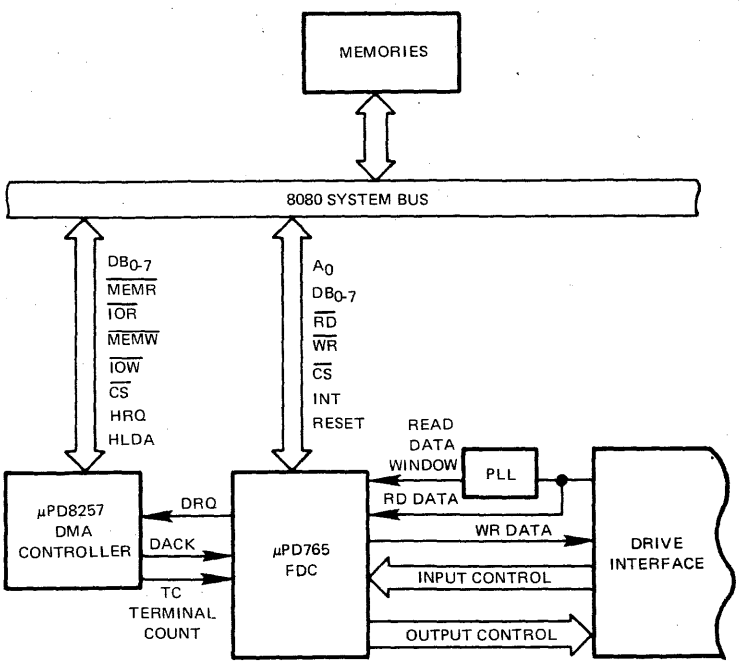
COMMAND SYMBOL DESCRIPTION



SYMBOL	NAME	DESCRIPTION
A_0		A_0 stands for control signal A_0 (pin 5)
C	Cylinder Number	C stands for the current/selected Cylinder (track) number 0 through 76 of the medium.
D	Data	D stands for the data pattern which is going to be written into a Sector.
D_7-D_0	Data Bus	8-bit Data Bus, where D_7 stands for a most significant bit, and D_0 stands for a least significant bit.
DTL	Data Length	When N is defined as 00, DTL stands for the data length which users are going to read out or write into the Sector.
EOT	End of Track	EOT stands for the final Sector number on a Cylinder.
GPL	Gap Length	GPL stands for the length of Gap 3 (excluding VCO Sync. Field).
H	Head Address	H stands for head number 0 or 1, as specified in ID field.
HD	Head	HD stands for a selected head number 0 or 1.
HLT	Head Load Time	HLT stands for the head load time in the FDD (2 to 256 ms in 2 ms increments).
HUT	Head Unload Time	HUT stands for the head unload time after a read or write operation has occurred (0 to 240 ms in 16 ms increments).
MF	FM or MFM Mode	If MF is low, FM mode is selected, and if it is high, MFM mode is selected.
MT	Multi-Track	If MT is high, a multi-track operation is to be performed. (A cylinder under both HD0 and HD1 will be read or written.)

©IC MASTER 1979

COMMAND SYMBOL DESCRIPTION (CONT.)

SYMBOL	NAME	DESCRIPTION
N	Number	N stands for the number of data bytes written in a Sector.
NCN	New Cylinder Number	NCN stands for a new Cylinder number, which is going to be reached as a result of the Seek operation. Desired position of Head.
ND	Non-DMA Mode	ND stands for operation in the Non-DMA Mode.
PCN	Present Cylinder Number	PCN stands for the Cylinder number at the completion of SENSE INTERRUPT STATUS Command. Position of Head at present time.
R	Record	R stands for the Sector number, which will be read or written.
R/W	Read/Write	R/W stands for either Read (R) or Write (W) signal.
SC	Sector	SC indicates the number of Sectors per Cylinder.
SK	Skip	SK stands for Skip Deleted Data Address Mark.
SRT	Step Rate Time	SRT stands for the Stepping Rate for the FDD. (1 to 16 ms in 1 ms increments.) Must be defined for each of the four drives.
ST 0 ST 1 ST 2 ST 3	Status 0 Status 1 Status 2 Status 3	ST 0-3 stand for one of four registers which store the status information after a command has been executed. This information is available during the result phase after command execution. These registers should not be confused with the main status register (selected by $A_0 = 0$). ST 0-3 may be read only after a command has been executed and contain information relevant to that particular command.
STP		During a Scan operation, if STP = 1, the data in contiguous sectors is compared byte by byte with data sent from the processor (or DMA); and if STP = 2, then alternate sectors are read and compared.
US	Unit Select	US stands for a selected drive number 0 or 1.

SYSTEM CONFIGURATION

©IC MASTER 1979

PROCESSOR INTERFACE

During Command or Result Phases the Main Status Register (described earlier) must be read by the processor before each byte of information is written into or read from the Data Register. Bits D6 and D7 in the Main Status Register must be in a 0 and 1 state, respectively, before each byte of the command word may be written into the μPD765. Many of the commands require multiple bytes, and as a result the Main Status Register must be read prior to each byte transfer to the μPD765. Also, bits 6 and 7 in the Status Register must appear as D6 = 0 and D7 = 1 before the byte transfer is executed. During the Result Phase, D6 and D7 in the Main Status Register must both be 1's (D6 = 1 and D7 = 1) before reading each byte from the Data Register. Note, this reading of the Main Status Register before each byte transfer to the μPD765 is required in only the Command and Result Phases, and NOT during the Execution Phase.

During the Execution Phase, the Main Status Register need not be read. If the μPD765 is in the NON-DMA Mode, then the receipt of each data byte (if μPD765 is reading data from FDD) is indicated by an Interrupt signal on pin 18 (INT = 1). The generation of a Read signal ($\overline{RD}$ = 0) will reset the Interrupt as well as output the Data onto the Data Bus. If the processor cannot handle interrupts fast enough (every 13 μs) then it may poll the Main Status Register and then bit D7 (ROM) functions just like the Interrupt signal. If a Write Command is in process then the $\overline{WR}$ signal performs the reset to the Interrupt signal.

If the μPD765 is in the DMA Mode, no Interrupts are generated during the Execution Phase. The μPD765 generates DRQ's (DMA Requests) when each byte of data is available. The DMA Controller responds to this request with both a $\overline{DACK}$ = 0 (DMA Acknowledge) and a $\overline{RD}$ = 0 (Read signal). When the DMA Acknowledge signal goes low ($\overline{DACK}$ = 0) then the DMA Request is reset (DRQ = 0). If a Write Command has been programmed then a $\overline{WR}$ signal will appear instead of $\overline{RD}$. After the Execution Phase has been completed (Terminal Count has occurred) then an Interrupt will occur (INT = 1). This signifies the beginning of the Result Phase. When the first byte of data is read during the Result Phase, the Interrupt is automatically reset (INT = 0).

It is important to note that during the Result Phase all bytes shown in the Command Table must be read. The Read Data Command, for example has seven bytes of data in the Result Phase. All seven bytes must be read in order to successfully complete the Read Data Command. The μPD765 will not accept a new command until all seven bytes have been read. Other commands may require fewer bytes to be read during the Result Phase.

The μPD765 contains five Status Registers. The Main Status Register mentioned above may be read by the processor at any time. The other four Status Registers (ST0, ST1, ST2, and ST3) are only available during the Result Phase, and may be read only after successfully completing a command. The particular command which has been executed determines how many of the Status Registers will be read.

The bytes of data which are sent to the μPD765 to form the Command Phase, and are read out of the μPD765 in the Result Phase, must occur in the order shown in the Command Table. That is, the Command Code must be sent first and the other bytes sent in the prescribed sequence. No foreshortening of the Command or Result Phases are allowed. After the last byte of data in the Command Phase is sent to the μPD765, the Execution Phase automatically starts. In a similar fashion, when the last byte of data is read out in the Result Phase, the command is automatically ended and the μPD765 is ready for a new command. A command may be truncated (prematurely ended) by simply sending a Terminal Count signal to pin 16 (TC = 1). This is a convenient means of ensuring that the processor may always get the μPD765's attention even if the disk system hangs up in an abnormal manner.

©IC MASTER 1979

READ DATA

A set of nine (9) byte words are required to place the FDC into the Read Data Mode. After the Read Data command has been issued the FDC loads the head (if it is in the unloaded state), waits the specified head settling time (defined in the Specify Command), and begins reading ID Address Marks and ID fields. When the current sector number ("R") stored in the ID Register (IDR) compares with the sector number read off the diskette, then the FDC outputs data (from the data field) byte-to-byte to the main system via the data bus.

After completion of the read operation from the current sector, the Sector Number is incremented by one, and the data from the next sector is read and output on the data bus. This continuous read function is called a "Multi-Sector Read Operation." The Read Data Command may be terminated by the receipt of a Terminal Count signal. Upon receipt of this signal, the FDC stops outputting data to the processor, but will continue to read data from the current sector, check CRC (Cyclic Redundancy Count) bytes, and then at the end of the sector terminate the Read Data Command.

The amount of data which can be handled with a single command to the FDC depends upon MT (multi-track), MF (MFM/FM), and N (Number of Bytes/Sector). Table 1 below shows the Transfer Capacity.

Multi-Track MT	MFM/FM MF	Bytes/Sector N	Maximum Transfer Capacity (Bytes/Sector) (Number of Sectors)	Final Sector Read from Diskette
0	0	00	(128) (26) = 3,328	26 at Side 0
0	1	01	(256) (26) = 6,656	26 at Side 1
1	0	00	(128) (52) = 6,656	26 at Side 1
1	1	01	(256) (52) = 13,312	
0	0	01	(256) (15) = 3,840	15 at Side 0
0	1	02	(512) (15) = 7,680	15 at Side 1
1	0	01	(256) (30) = 7,680	15 at Side 1
1	1	02	(512) (30) = 15,360	
0	0	02	(512) (8) = 4,096	8 at Side 0
0	1	03	(1024) (8) = 8,192	8 at Side 1
1	0	02	(512) (16) = 8,192	8 at Side 1
1	1	03	(1024) (16) = 16,384	

Table 1. Transfer Capacity

The "multi-track" function (MT) allows the FDC to read data from both sides of the diskette. For a particular cylinder, data will be transferred starting at Sector 0, Side 0 and completing at Sector L, Side 1 (Sector L = last sector on the side). Note, this function pertains to only one cylinder (the same track) on each side of the diskette.

When N = 0, then DTL defines the data length which the FDC must treat as a sector. If DTL is smaller than the actual data length in a Sector, the data beyond DTL in the Sector, is not sent to the Data Bus. The FDC reads (internally) the complete Sector performing the CRC check, and depending upon the manner of command termination, may perform a Multi-Sector Read Operation. When N is non-zero, then DTL has no meaning.

At the completion of the Read Data Command, the head is not unloaded until after Head Unload Time Interval (specified in the Specify Command) has elapsed. If the processor issues another command before the head unloads then the head settling time may be saved between subsequent reads. This time out is particularly valuable when a diskette is copied from one drive to another.

If the FDC reads all the data in the final sector of a cylinder and the read operation is not terminated by the processor, then the FDC sets the EN (End of Cylinder) flag in Status Register 1 to a 1 (high), and terminates the Read Data Command.

If the FDC detects the Index Hole twice without finding the right sector, (indicated in "R"), then the FDC sets the ND (No Data) flag in Status Register 1 to a 1 (high), and terminates the Read Data Command.

After reading the ID and Data Fields in each sector, the FDC checks the CRC bytes. If a read error is detected (incorrect CRC in ID field), the FDC sets the DE (Data Error) flag in Status Register 1 to a 1 (high), and if a CRC error occurs in the Data Field the FDC also sets the DD (Data Error in Data Field) flag in Status Register 2 to a 1 (high), and terminates the Read Data Command.

If the FDC reads a Deleted Data Address Mark off the diskette, and the SK bit (bit D5 in the first Command Word) is not set (SK = 0), then the FDC sets the DM (Control Mark) flag in Status Register 2 to a 1 (high), and terminates the Read Data Command, after reading all the data in the Sector. If SK = 1, the FDC skips the sector with the Deleted Data Address Mark and reads the next sector.

During disk data transfers between the FDC and the processor, via the data bus, the FDC must be serviced by the processor every 27 μs in the FM Mode, and every 13 μs in the MFM Mode, or the FDC sets the OR (Over Run) flag in Status Register 1 to a 1 (high), and terminates the Read Data Command.

If the processor terminates a read (or write) operation in the FDC, then the ID Information in the Result Phase is dependent upon the state of the MT bit and EOT byte. Table 2 shows the values for C, H, R, and N, when the processor terminates the Command.

©IC MASTER 1979

FUNCTIONAL DESCRIPTION OF COMMANDS (CONT.)

MT	EOT	Final Sector Transferred to Processor	ID Information at Result Phase			
			C	N	R	N
0	1A	Sector 1 to 25 at Side 0	NC	NC	R + 1	NC
	0F	Sector 1 to 14 at Side 0				
	08	Sector 1 to 7 at Side 0				
	1A	Sector 26 at Side 0	C + 1	NC	R = 01	NC
	0F	Sector 15 at Side 0				
	08	Sector 8 at Side 0				
	1A	Sector 1 to 25 at Side 1	NC	NC	R + 1	NC
	0F	Sector 1 to 14 at Side 1				
	08	Sector 1 to 7 at Side 1				
	1A	Sector 26 at Side 1	C + 1	NC	R = 01	NC
	0F	Sector 15 at Side 1				
	08	Sector 8 at Side 1				
1	1A	Sector 1 to 25 at Side 0	NC	NC	R + 1	NC
	0F	Sector 1 to 14 at Side 0				
	08	Sector 1 to 7 at Side 0				
	1A	Sector 26 at Side 0	NC	$\overline{LSB}$	R = 01	NC
	0F	Sector 15 at Side 0				
	08	Sector 8 at Side 0				
	1A	Sector 1 to 25 at Side 1	NC	NC	R + 1	NC
	0F	Sector 1 to 14 at Side 1				
	08	Sector 1 to 7 at Side 1				
	1A	Sector 26 at Side 1	C + 1	$\overline{LSB}$	R = 01	NC
	0F	Sector 15 at Side 1				
	08	Sector 8 at Side 1				

Notes: ① NC (No Change): The same value as the one at the beginning of command execution.

② LSB (Least Significant Bit): The least significant bit of H is complemented.

Table 2: ID Information When Processor Terminates Command

WRITE DATA

A set of nine (9) bytes are required to set the FDC into the Write Data mode. After the Write Data command has been issued the FDC loads the head (if it is in the unloaded state), waits the specified heat settling time (defined in the Specify Command), and begins reading ID Fields. When the current sector number ("R"), stored in the ID Register (IDR) compares with the sector number read off the diskette, then the FDC takes data from the processor byte-by-byte via the data bus, and outputs it to the FDD.

After writing data into the current sector, the Sector Number stored in "R" is incremented by one, and the next data field is written into. The FDC continues this "Multi-Sector Write Operation" until the issuance of a Terminal Count signal. If a Terminal Count signal is sent to the FDC it continues writing into the current sector to complete the data field. If the Terminal Count signal is received while a data field is being written then the remainder of the data field is filled with 00 (zeros).

The FDC reads the ID field of each sector and checks the CRC bytes. If the FDC detects a read error (incorrect CRC) in one of the ID Fields, it sets the DE (Data Error) flag of Status Register 1 to a 1 (high), and terminates the Write Data Command. (Status Register 0 also has bits 7 and 6 set to 0 and 1 respectively.)

The Write Command operates in much the same manner as the Read Command. The following items are the same, and one should refer to the Read Data Command for details:

- Transfer Capacity
- EN (End of Cylinder) Flag
- ND (No Data) Flag
- Head Unload Time Interval
- ID Information when the processor terminates command (see Table 2)
- Definition of DTL when N = 0 and when N ≠ 0

In the Write Data mode, data transfers between the processor and FDC, via the Data Bus, must occur every 31 μs in the FM mode, and every 15 μs in the MFM mode. If the time interval between data transfers is longer than this then the FDC sets the OR (Over Run) flag in Status Register 1 to a 1 (high), and terminates the Write Data Command. (Status Register 0 also has bit 7 and 6 set to 0 and 1 respectively.)

WRITE DELETED DATA

This command is the same as the Write Data Command except a Deleted Data Address Mark is written at the beginning of the Data Field instead of the normal Data Address Mark.

READ DELETED DATA

This command is the same as the Read Data Command except that when the FDC detects a Data Address Mark at the beginning of a Data Field (and SK = 0 (low), it will read all the data in the sector and set the DM flag in Status Register 2 to a 1 (high), and then terminate the command. If SK = 1, then the FDC skips the sector with the Data Address Mark and reads the next sector.

©IC MASTER 1979

READ A TRACK

This command is similar to READ DATA Command except that this is a continuous READ operation where the entire contents of the track are read. Immediately after encountering the INDEX HOLE, the FDC starts reading all data on the track, Gap bytes, Address Marks and Data are all read as a continuous data stream. If the FDC finds an error in the ID or DATA CRC check bytes, it continues to read data from the track. The FDC compares the ID information read from each sector with the value stored in the IDR, and sets the ND flag of Status Register 1 to a 1 (high) if there is no comparison. Multi-track or skip operations are not allowed with this command.

This command terminates when EOT number of sectors have been read ($EOT_{max} = FF_{hex} = 255_{dec}$). If the FDC does not find an ID Address Mark on the diskette after it encounters the INDEX HOLE for the second time, then it sets the MA (missing address mask) flag in Status Register 1 to a 1 (high), and terminates the command.

READ ID

The READ ID Command is used to give the present position of the recording head. The FDC stores the values from the first ID Field it is able to read. If no proper ID Address Mark is found on the diskette, before the INDEX HOLE is encountered for the second time then the MA (Missing Address Mark) flag in Status Register 1 is set to a 1 (high), and if no data is found then the ND (No Data) flag is also set in Status Register 1 to a 1 (high). The command is then terminated with Bits 7 and 6 in Status Register 0 set to 0 and 1 respectively.

FORMAT A TRACK

The Format Command allows an entire track to be formatted. After the INDEX HOLE is detected, Data is written on the Diskette; Gaps, Address Marks, ID Fields and Data Fields, all per the IBM System 34 (Double Density) or System 3740 (Single Density) Format are recorded. The particular format which will be written is controlled by the values programmed into N (number of bytes/sector), SC (sectors-cylinder), GPL (Gap Length), and D (Data Pattern) which are supplied by the processor during the Command Phase. The Data Field is filled with the Byte of data stored in D. The ID Field for each sector is supplied by the processor; that is, four data requests per sector are made by the FDC for C (Cylinder Number), H (Head Number), R (Sector Number) and N (Number of Bytes/Sector). This allows the diskette to be formatted with non-sequential sector numbers, if desired.

After formatting each sector, the processor must send new values for C, H, R, and N to the μPD765 for each sector on the track. The contents of the R register is incremented by one after each sector is formatted, thus, the R register contains a value of R + 1 when it is read during the Result Phase. This incrementing and formatting continues for the whole cylinder until the FDC encounters the INDEX HOLE for the second time, whereupon it terminates the command.

If a FAULT signal is received from the FDD at the end of a write operation, then the FDC sets the EC flag of Status Register 0 to a 1 (high), and terminates the command after setting bits 7 and 6 of Status Register 0 to 0 and 1 respectively. Also the loss of a READY signal at the beginning of a command execution phase causes bits 7 and 6 of Status Register 0 to be set to 0 and 1 respecitvely.

Table 3 shows the relationship between N, SC, and GPL for various sector sizes:

FORMAT	SECTOR SIZE	N	SC	GPL ①	GPL ②	REMARKS
FM Mode	128 bytes/Sector	00	$1A_{(16)}$	.07	$1B_{(16)}$	IBM Diskette 1
	256	01	$0F_{(16)}$	$OE_{(16)}$	$2A_{(16)}$	IBM Diskette 2
	512	02	08	$1B_{(16)}$	$3A_{(16)}$	
FM Mode	1024 bytes/Sector	03	04	–	–	
	2048	04	02	–	–	
	4096	05	01	–	–	
MFM Mode	256	01	$1A_{(16)}$	$OE_{(16)}$	$36_{(16)}$	IBM Diskette 2D
	512	02	$0F_{(16)}$	$1B_{(16)}$	$54_{(16)}$	
	1024	03	08	$35_{(16)}$	$74_{(16)}$	IBM Diskette 2D
	2048	04	04	–	–	
	4096	05	02	–	–	
	8192	06	01	–	–

Note: ① Suggested values of GPL in Read or Write Commands to avoid splice point between data field and ID field of contiguous sections.

② Suggested values of GPL in format command.

©IC MASTER 1979

FUNCTIONAL DESCRIPTION OF COMMANDS (CONT.)

SCAN COMMANDS

The SCAN Commands allow data which is being read from the diskette to be compared against data which is being supplied from the main system (Processor in NON-DMA mode, and DMA Controller in DMA mode). The FDC compares the data on a byte-by-byte basis, and looks for a sector of data which meets the conditions of $D_{FDD} = D_{Processor}$, $D_{FDD} \leq D_{Processor}$, or $D_{FDD} \geq D_{Processor}$. Ones complement arithmetic is used for comparison (FF = largest number, 00 = smallest number). After a whole sector of data is compared, if the conditions are not met, the sector number is incremented (R + STP → R), and the scan operation is continued. The scan operation continues until one of the following conditions occur; the conditions for scan are met (equal, low, or high), the last sector on the track is reached (EOT), or the terminal count signal is received.

If the conditions for scan are met then the FDC sets the SH (Scan Hit) flag of Status Register 2 to a 1 (high), and terminates the Scan Command. If the conditions for scan are not met between the starting sector (as specified by R) and the last sector on the cylinder (EOT), then the FDC sets the SN (Scan Not Satisfied) flag of Status Register 2 to a 1 (high), and terminates the Scan Command. The receipt of a TERMINAL COUNT signal from the Processor or DMA Controller during the scan operation will cause the FDC to complete the comparison of the particular byte which is in process, and then to terminate the command. Table 4 shows the status of bits SH and SN under various conditions of SCAN.

COMMAND	STATUS REGISTER 2		COMMENTS
	BIT 2 = SN	BIT 3 = SH	
Scan Equal	0	1	$D_{FDD} = D_{Processor}$
	1	0	$D_{FDD} \neq D_{Processor}$
Scan Low or Equal	0	1	$D_{FDD} = D_{Processor}$
	0	0	$D_{FDD} < D_{Processor}$
	1	0	$D_{FDD} \not< D_{Processor}$
Scan High or Equal	0	1	$D_{FDD} = D_{Processor}$
	0	0	$D_{FDD} < D_{Processor}$
	1	0	$D_{FDD} \not> D_{Processor}$

Table 4

If the FDC encounters a Deleted Data Address Mark on one of the sectors (and SK = 0), then it regards the sector as the last sector on the cylinder, sets CM (Control Mark) flag of Status Register 2 to a 1 (high) and terminates the command. If SK = 1, the FDC skips the sector with the Deleted Address Mark, and reads the next sector. In the second case (SK = 1), the FDC sets the CM (Control Mark) flag of Status Register 2 to a 1 (high) in order to show that a Deleted Sector had been encountered.

When either the STP (contiguous sectors = 01, or alternate sectors = 02 sectors are read) or the MT (Multi-Track) are programmed, it is necessary to remember that the last sector on the track must be read. For example, if STP = 02, MT = 0, the sectors are numbered sequentially 1 through 26, and we start the Scan Command at sector 21; the following will happen. Sectors 21, 23, and 25 will be read, then the next sector (26) will be skipped and the Index Hole will be encountered before the EOT value of 26 can be read. This will result in an abnormal termination of the command. If the EOT had been set at 25 or the scanning started at sector 20, then the Scan Command would be completed in a normal manner.

During the Scan Command data is supplied by either the processor or DMA Controller for comparison against the data read from the diskette. In order to avoid having the OR (Over Run) flag set in Status Register 1, it is necessary to have the data available in less than 27 μs (FM Mode) or 13 μs (MFM Mode). If an Overrun occurs the FDC ends the command with bits 7 and 6 of Status Register 0 set to 0 and 1, respectively.

SEEK

The read/write head within the FDD is moved from track to track under control of the Seek Command. The FDC compares the PCN (Present Cylinder Number) which is the current head position with the NCN (New Cylinder Number), and if there is a difference performs the following operation:

PCN < NCN: Direction signal to FDD set to a 1 (high), and Step Pulses are issued.
PCN > NCN: Direction signal to FDD set to a 0 (low), and Step Pulses are issued.

The rate at which Step Pulses are issued is controlled by SRT (Stepping Rate Time) in the SPECIFY Command. After each Step Pulse is issued NCN is compared against PCN, and when NCN = PCN, then the SE (Seek End) flag is set in Status Register 0 to a 1 (high), and the command is terminated.

During the Command Phase of the Seek operation the FDC is in the FDC BUSY state, but during the Execution Phase it is in the NON BUSY state. While the FDC is in the NON BUSY state, another Seek Command may be issued, and in this manner parallel seek operations may be done on up to 4 Drives at once.

If a FDD is in a NOT READY state at the beginning of the command execution phase or during the seek operation, then the NR (NOT READY) flag is set in Status Register 0 to a 1 (high), and the command is terminated after bits 7 and 6 of Status Register 0 are set to 0 and 1 respectively.

©IC MASTER 1979

RECALIBRATE

The function of this command is to retract the read/write head within the FDD to the Track 0 position. The FDC clears the contents of the PCN counter, and checks the status of the Track 0 signed signal from the FDD. As long as the Track 0 signal is low, the Direction signal remains 1 (high) and Step Pulses are issued. When the Track 0 signal goes high, the SE (SEEK END) flag in Status Register 0 is set to a 1 (high) and the command is terminated. If the Track 0 signal is still low after 77 Step Pulse have been issued, the FDC sets the SE (SEEK END) and EC (EQUIPMENT CHECK) flags of Status Register 0 to both 1s (highs), and terminates the command after bits 7 and 6 of Status Register 0 is set to 0 and 1 respectively.

The ability to do overlap RECALIBRATE Commands to multiple FDDs and the loss of the READY signal, as described in the SEEK Command, also applies to the RECALIBRATE Command.

SENSE INTERRUPT STATUS

An Interrupt signal is generated by the FDC for one of the following reasons:

1. Upon entering the Result Phase of:
   a. Read Data Command
   b. Read a Cylinder Command
   c. Read ID Command
   d. Read Deleted Data Command
   e. Write Data Command
   f. Format a Cylinder Command
   g. Write Deleted Data Command
   h. Scan Commands
2. Ready Line of FDD changes state
3. End of Seek or Recalibrate Command
4. During Execution Phase in the NON-DMA Mode

Interrupts caused by reasons 1 and 4 above occur during normal command operations and are easily discernible by the processor. However, interrupts caused by reasons 2 and 3 above may be uniquely identified with the aid of the Sense Interrupt Status Command. This command when issued resets the interrupt signal and via bits 5, 6, and 7 of Status Register 0 identifies the cause of the interrupt.

SEEK END BIT 5	INTERRUPT CODE		CAUSE
	BIT 6	BIT 7	
0	1	1	Ready Line changed state, either polarity
1	0	0	Normal Termination of Seek or Recalibrate Command
1	1	0	Abnormal Termination of Seek or Recalibrate Command

Table 5

Neither the Seek or Recalibrate Command have a Result Phase. As a result it is mandatory to use the Sense Interrupt Status Command after these commands to effectively terminate them and to provide verification of where the head is positioned (PCN).

SPECIFY

The Specify Command sets the initial values for each of the three internal timers. The HUT (Head Unload Time) defines the time from the end of the Execution Phase of one of the Read/Write Commands to the head unload state. This timer is programmable from 0 to 240 ms in increments of 16 ms (00 = 0 ms, 01 = 16 ms, 02 = 32 ms, etc.). The SRT (Step Rate Time) defines the time interval between adjacent step pulses. This timer is programmable from 1 to 16 ms in increments of 1 ms (01 = 1 ms, 02 = 2 ms, 03 = 3 ms, etc.). The HLT (Head Load Time) defines the time between when the Head Load signal goes high and when the Read/Write operation starts. This timer is programmable from 2 to 256 ms in increments of 2 ms (00 = 2 ms, 01 = 4 ms, 02 = 6 ms, etc.).

The time intervals mentioned above are a direct function of the clock (CLK on pin 19). Times indicated above are for an 8 MHz clock, if the clock was reduced to 4 MHz (mini-floppy application) then all time intervals are increased by a factor of 2.

The choice of DMA or NON-DMA operation is made by the ND (NON-DMA) bit. When this bit is high (ND = 1) the NON-DMA mode is selected, and when ND = 0 the DMA mode is selected.

SENSE DRIVE STATUS

This command may be used by the processor whenever it wishes to obtain the status of the FDDs.

INVALID

If an invalid command is sent to the FDC (a command not defined above), then the FDC will terminate the command after bits 7 and 6 of Status Register 0 are set to 1 and 0 respectively. **A Sense Interrupt Status Command must be sent after Seek or Recalibrate Commands, otherwise the FDC will consider the next command to be an Invalid Command.**

In some applications the user may wish to use this command as a No-Op command, to place the FDC in a standby or no operation state.

STATUS REGISTER IDENTIFICATION

BIT NO.	BIT NAME	BIT SYMBOL	DESCRIPTION
STATUS REGISTER 0			
D_7	Interrupt Code	IC	$D_7 = 0$ and $D_6 = 0$ Normal Termination of Command, (NT). Command was completed and properly executed.
D_6			$D_7 = 0$ and $D_6 = 1$ Abnormal Termination of Command, (AT). Execution of Command was started, but was not successfully completed.
			$D_7 = 1$ and $D_6 = 0$ Invalid Command issue, (IC). Command which was issued was never started.
			$D_7 = 1$ and $D_6 = 1$ Abnormal Termination because during command execution the ready signal from FDD changed state.
D_5	Seek End	SE	When the FDC completes the SEEK Command, this flag is set to 1 (high).
D_4	Equipment Check	EC	If a fault Signal is received from the FDD, or if the Track 0 Signal fails to occur after 77 Step Pulses (Recalibrate Command) then this flag is set.
D_3	Not Ready	NR	When the FDD is in the not-ready state and a read or write command is issued, this flag is set. If a read or write command is issued to Side 1 of a single sided drive, then this flag is set.
D_2	Head Address	HD	This flag is used to indicate the state of the head at Interrupt.
D_1	Unit Select 0	US 0	These flags are used to indicate a Drive Unit Number at Interrupt
D_0	Unit Select 1	US 1	
STATUS REGISTER 1			
D_7	End of Cylinder	EN	When the FDC tries to access a Sector beyond the final Sector of a Cylinder, this flag is set.
D_6			Not used. This bit is always 0 (low).
D_5	Data Error	DE	When the FDC detects a CRC error in either the ID field or the data field, this flag is set.
D_4	Over Run	OR	If the FDC is not serviced by the main-systems during data transfers, within a certain time interval, this flag is set.
D_3			Not used. This bit always 0 (low).
D_2	No Data	ND	During execution of READ DATA, WRITE DELETED DATA or SCAN Command, if the FDC cannot find the Sector specified in the IDR Register, this flag is set.
			During executing the READ ID Command, if the FDC cannot read the ID field without an error, then this flag is set.
			During the execution of the READ A Cylinder Command, if the starting sector cannot be found, then this flag is set.

STATUS REGISTER IDENTIFICATION (CONT.)

BIT NO.	BIT NAME	BIT SYMBOL	DESCRIPTION
STATUS REGISTER 1 (CONT.)			
D_1	Not Writable	NW	During execution of WRITE DATA, WRITE DELETED DATA or Format A Cylinder Command, if the FDC detects a write protect signal from the FDD, then this flag is set.
D_0	Missing Address Mark	MA	If the FDC cannot detect the ID Address Mark after encountering the index hold twice, then this flag is set.
			If the FDC cannot detect the Data Address Mark or Deleted Data Address Mark, this flag is set. Also at the same time, the MD (Missing Address Mark in Data Field) of Status Register 2 is set.
STATUS REGISTER 2			
D_7			Not used. This bit is always 0 (low).
D_6	Control Mark	CM	During executing the READ DATA or SCAN Command, if the FDC encounters a Sector which contains a Deleted Data Address Mark, this flag is set.
D_5	Data Error in Data Field	DD	If the FDC detects a CRC error in the data field then this flag is set.
D_4	Wrong Cylinder	WC	This bit is related with the ND bit, and when the contents of C on the medium is different from that stored in the IDR, this flag is set.
D_3	Scan Equal Hit	SH	During execution, the SCAN Command, if the condition of "equal" is satisfied, this flag is set.
D_2	Scan Not Satisfied	SN	During executing the SCAN Command, if the FDC cannot find a Sector on the cylinder which meets the condition, then this flag is set.
D_1	Bad Cylinder	BC	This bit is related with the ND bit, and when the content of C on the medium is different from that stored in the IDR and the content of C is FF, then this flag is set.
D_0	Missing Address Mark in Data Field	MD	When data is read from the medium, if the FDC cannot find a Data Address Mark or Deleted Data Address Mark, then this flag is set.
STATUS REGISTER 3			
D_7	Fault	FT	This bit is used to indicate the status of the Fault signal from the FDD.
D_6	Write Protected	WP	This bit is used to indicate the status of the Write Protected signal from the FDD.
D_5	Ready	RY	This bit is used to indicate the status of the Ready signal from the FDD.
D_4	Track 0	T0	This bit is used to indicate the status of the Track 0 signal from the FDD.
D_3	Two Side	TS	This bit is used to indicate the status of the Two Side signal from the FDD.
D_2	Head Address	HD	This bit is used to indicate the status of Side Select signal to the FDD.
D_1	Unit Select 1	US 1	This bit is used to indicate the status of the Unit Select 1 signal to the FDD.
D_0	Unit Select 0	US 0	This bit is used to indicate the status of the Unit Select 0 signal to the FDD.

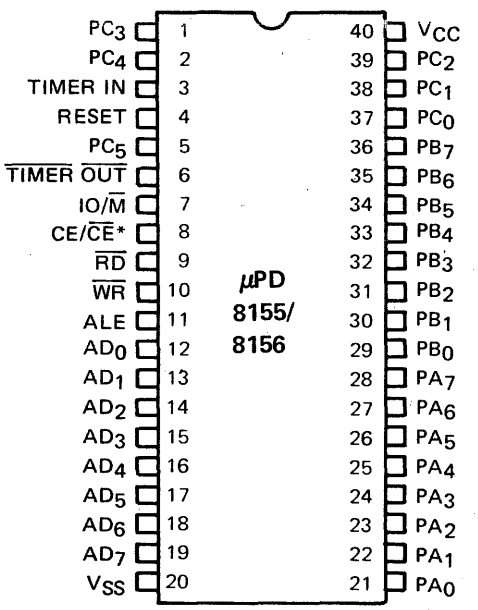
NEC
μPD8155
μPD8156

2048 BIT STATIC MOS RAM WITH I/O PORTS AND TIMER



DESCRIPTION

The μPD8155 and μPD8156 are μPD8085A family components having 256 X 8 Static RAM, 3 programmable I/O ports and a programmable timer. They directly interface to the multiplexed μPD8085A bus with no external logic. The μPD8155 has an active low chip enable while the μPD8156 is active high.

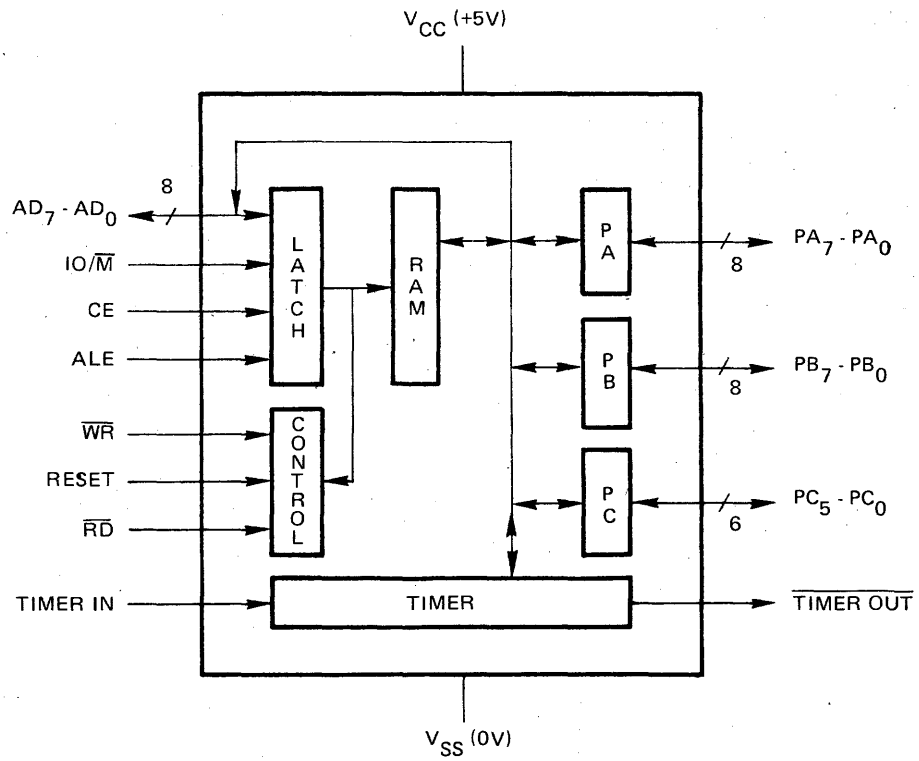
FEATURES

- 256 X 8-Bit Static RAM
- Two Programmable 8-Bit I/O Ports
- One Programmable 6-Bit I/O Port
- Single Power Supplies: +5 Volt
- Directly Interfaces to the μPD8085A
- Available in 40 Pin Plastic Packages

PIN CONFIGURATION

*μPD8155: $\overline{CE}$
μPD8156: CE

©IC MASTER 1979



FUNCTIONAL DESCRIPTION

The μPD8155 and μPD8156 contain 2048 bits of Static RAM organized as 256 X 8. The 256 word memory location may be selected anywhere within the 64K memory space by using combinations of the upper 8 bits of address from the μPD8085A as a chip select.

The two general purpose 8-bit ports (PA and PB) may be programmed for input or output either in interrupt or status mode. The single 6-bit port (PC) may be used as control for PA and PB or general purpose input or output port. The μPD8155 and μPD8156 are programmed for their system personalities by writing into their Command/Status Registers (C/S) upon system initialization.

The timer is a single 14-bit down counter which is programmable for 4 modes of operation; see Timer Section.

BLOCK DIAGRAM

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	0°C to +70°C
Storage Temperature (Plastic Package)	-40°C to +125°C
Voltage on Any Pin	-0.3 to +7 Volts①
Power Dissipation	1.5 W

Note: ① With Respect to Ground.

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

*T_a = 25°C

COMMAND STATUS REGISTER

The Command Status Register is an 8-bit register which must be programmed before the μPD8155/8156 may perform any useful functions. Its purpose is to define the mode of operation for the three ports and the timer. Programming of the device may be accomplished by writing to I/O address XXXXX000 (X denotes don't care) with a specific bit pattern. Reading of the Command Status Register can be accomplished by performing an I/O read operation at address XXXXX000. The pattern returned will be a 7-bit status report of PA, PB and the Timer. The bit patterns for the Command Status Register are defined as follows:

COMMAND STATUS WRITE

TM2	TM1	IEB	IEA	PC_2	PC_1	PB	PA

where:

TM2-TM1	Define Timer Mode
IEB	Enable Port B Interrupt
IEA	Enable Port A Interrupt
PC_2-PC_1	Define Port C Mode
PB/PA	Define Port B/A as In or Out ①

The Timer mode of operation is programmed as follows during command status write:

TM2	TM1	TIMER MODE
0	0	Don't Affect Timer Operation
0	1	Stop Timer Counting
1	0	Stop Counting after TC
1	1	Start Timer Operation

Interrupt enable status is programmed as follows:

IEB/IEA	INTERRUPT ENABLE PORT B/A
0	No
1	Yes

Port C may be placed in four possible modes of operation as outlined below. The modes are selected during command status write as follows:

PC_2	PC_1	PORT C MODE
0	0	ALT 1
0	1	ALT 3
1	0	ALT 4
1	1	ALT 2

The function of each pin of port C in the four possible modes is outlined as follows:

PIN	ALT 1	ALT 2	ALT 3 ②	ALT 4 ②
PC0	IN	OUT	A INTR	A INTR
PC1	IN	OUT	A BF	A BF
PC2	IN	OUT	A $\overline{STB}$	A $\overline{STB}$
PC3	IN	OUT	OUT	B INTR
PC4	IN	OUT	OUT	B BF
PC5	IN	OUT	OUT	B $\overline{STB}$

Notes: ① PB/PA Sets Port B/A Mode: 0 = Input; 1 = Output

② In ALT 3 and ALT 4 mode the control signals are initialized as follows:

CONTROL	INPUT	OUTPUT
$\overline{STB}$ (Input Strobe)	Input Control	Input Control
INTR (Interrupt Request)	Low	High
BF (Buffer Full)	Low	Low

©IC MASTER 1979

COMMAND STATUS REGISTER (CONT.)

COMMAND STATUS READ

	TI	INTE B	B BF	INTR B	INTE A	A BF	INTR A

Where the function of each bit is as follows:

TI	Defines a Timer Interrupt. Latched high at TC and reset after reading the CS register or starting a new count.
INTE B/A	Defines If Port B/A Interrupt is Enabled. High = enabled.
B/A BF	Defines If Port B/A Buffer is Full-Input Mode or Empty-Output Mode. High = active.
INTR B/A	Port B/A Interrupt Request. High = active.

The programming address summary for the status, ports, and timer are as follows:

I/O Address	Number of Bits	Function
XXXXX000	8	Command Status
XXXXX001	8	PA
XXXXX010	8	PB
XXXXX011	6	PC
XXXXX100	8	Timer-Low
XXXXX101	8	Timer-High

TIMER
